7235. And therefore, though chemical tables shows like quantities, you consider that the qualities should be shown separately?—Yes.

7236. May I ask you in what way do you look an it and determine the value of this organic nitrogen it those two systems of waters?—If a certain quantity of water is allowed to stand at a temperature favourable to the development of the lower forms of organic life, it will be seen which water prodnces the most, and whether the quality is different in the different waters. The probability is that mountain water will show little or nothing, and the plain water may show a very decided amount, so far as I know; it certainly will in the lower part of the Thames, but it will not at the very beginning of the Thames—for example, at the Seven Springs, near Cheltenham. But I think it important to try that experiment on all the waters, and compare the animalcular forms which are developed in each.

7237. I see that in the water supplied to Manchester the quantity of organic nitrogen is ·026, and the quantity in the Thames water delivered by some of the companies is ·011, therefore less than half the quantity in the Manchester waters; but, notwithstanding the quantity which you have in those Manchester waters, as shown by chemical analysis, you seem to think that there are other points to be considered beyond the mere fact of the presence of organic nitrogen?—Yes.

7238. As you reside in Manchester, you are well acquainted with all the properties of the water there. Looking at those two waters as keeping waters, supposing you were to place them both under the same conditions, and both under a certain exposure, and to keep them for a long time, have you any knowledge of the result which would be produced in the two cases?—My opinion is that the mountain water will keep best.

7239. The water supplied to Manchester is collected upon the hills?—Yes, on the hills between Lancashire and Yorkshire.

7240. How does that water keep?—I have not had occasion to keep any of that water so long as some of the other waters. I have kept the waters from the Scotch hills when I was making an examination

for Glasgow, and I have also kept the water from the Thames when I was making the examination for the Metropolitan Sanitary Commission; but I have not made the same experiments so carefully for Manchester; I never knew of any large development of animalcular life from the Manchester water, except when it comes down muddy, which has been the case lately. I think they have been making some changes in the works, and it is difficult in such a case to compare it. However, as a rule, I believe the mountain water will keep very much better than the plain water above alluded to. I feel satisfied of that.

7241. You were mentioning some of the results you obtained from an examination of the Thames water which you made some years ago, taking the water above certain towns and below certain towns, with regard to the extent to which the water becomes oxidised and purified after a certain length of flow; could you mention those results?—There were a few points in the report published by the Sanitary Commission which I would mention. I say in that report: "The Thames water is at first pure as far as freedom "from organic matter is concerned, and takes its course "through a rather level country. The stream is soon "filled with plants, and at Kemble the water has "already taken up some organic matter, enough to "form a slight green deposit on standing. The water "here is still beautiful and clear, and is good water. "It is 15·5 degrees of hardness. When we come "down to Pangbourne the water cannot be said to "have become much worse. It is still so pure as to "require a considerable time to form a deposit, and "that only small, containing a few plants and some "small animalcules from $\frac{1}{2000}$ths to $\frac{1}{3000}$ths of an inch. "Here is a slight, but still decided trace of organic "matter from animals. There has been an increase "in the hardness also."

7242. Are we to understand you that you would be guided as to the objectionable quantity of organic matter in water rather by the results showing the development of animalculæ than by the results of chemical analysis?—I think that one of the most important experiments that can be made, although I would not neglect the others. I have seen some very striking instances, indeed, in which an enormous number of animalcules have been found in water which at first appeared perfectly pure, and quite a contrary result has taken place in water which I thought to be inferior.

7243. Both waters showing the presence of organic nitrogen, but giving rise to different living organisms?—Yes. That is nitrogen, which I suppose we must call organic; formerly I imagined it to be inorganic from these peculiarities which I suppose to exist.

7244. I understand you also to say that if you give the water a sufficient length of flow this organic matter will be oxidised more or less completely?—Yes, that is always the case. It is a question of length of flow, or length of storage, or depth of drainage; those are the three most important points.

7245. Do you consider that the presence of nitrates or nitrites is an indication of sewage having previously existed in the water?—Whenever the original water was free from nitrates, the nitrates in the succeeding flow of water may be taken as a proof of previous sewage, and more than that, I should say that they were the minimum of previous sewage, because some may have disappeared entirely. For example, though the upper part of the Thames showed no nitrates whatever, and the lower part of the Thames showed nitrates, we may say that they indicate a certain amount of sewage which had flowed into the Thames; but there may have been much more passed into the Thames which has not appeared in the form of nitrates.

7246. Might not that also to a certain extent arise from vegetable matter as well as from animal matter?—Yes. The nitrites and nitrates are formed from albumenoid matter decomposed, whether arising from animals or vegetables. I have endeavoured to tell whether it comes from animals or vegetables, and I think in some cases we are able to tell.

7247. By what means?—The nitrates are what I have called old organic matter. There is no doubt that by the oxydation of nitrogen compounds nitric acid is formed. I imitated this process long ago, using chiefly yeast, and so produced nitrates from yeast or vegetable matter The nitrate comes from animal and vegetable albumenoids indifferently. When estimating the London sewage we may readily refer most, if not all of it to animal matter or sewage. In the river above London some of the nitrates come I do not doubt from vegetable matter. I have not estimated how much comes from one and how much from the others. I am inclined to think that nitrates coming down may be divided into the animal and vegetable nitrates, and measured. Albumen, &c., would produce nitrates without being used by animals. When nitrates are caused by matter from animals there is always a corresponding amount of common salt. Men take from 200 to 300 grains at least of common salt every day, and it is given out every day. This is the most unchangeable accompaniment of sewage. By it we may know how much sewage has existed, and how much of it has evaporated, if we know the original amount of water. By looking for this substance alone we may trace with great rapidity the increase of actual sewage in the Thames, and we may save ourselves some horror by remembering that some of the nitrates may be derived from vegetable matter. I do not doubt that all grass will give out this oxidised nitrogen. The amount of chlorides in sewage is somewhat about five per cent. of the dried matter, and the London waters contain about four-tenths of a grain per gallon more than the Manchester water. If all comes from sewage it would indicate a large amount, perhaps from 800,000 lbs. to 1,000,000 lbs. per day; but I do not think this calculation is of much value till I look into the details. This matter does not all come into the water, only the salts and such organic parts as escape filtration and oxidation. Nitrates act as manure; they are therefore decomposed. They do not therefore necessarily give the whole truth. If the original matter is free from nitrates, these accumulating, give the minimum of previous sewage. This remark will apply to Dr. Frankland's numbers, which would be the minimum of previous sewage in waters which had at first no nitrates. They cannot, therefore, be exaggerations if done with his usual accuracy. There are some difficult cases to explain where nitrates appear when we cannot find sewage. The nitrates from old beds of nitre would be scarcely considered as indicating previous sewage, as the animals have been so long dead. But there may be modes of forming nitre in the earth, as there is certainly in the air, without sewage. This difficulty cannot be said to appear in the case of the Thames water, at least the examination for chlorine would check it. There are said to be nitrates from many of the deep wells in which we cannot trace sewage. I do not understand that subject; I think it requires attention. We may say, why do we dislike nitrates, since they indicate aeration? They are disliked because of their previous bad company. They have been in contact with sewage when they can be shown to be formed recently. If, however, we are sure that the company is to be kept out we do not require to be afraid of such reformed characters unless they become personally offensive. As to their becoming personally offensive, I made a few experiments some time ago, and I thought that I could taste $1\frac{1}{2}$ grain of nitrate in the gallon, sufficiently to render the water vapid and insipid, but some more delicate tastes may be affected by a less amount than $1\frac{1}{2}$ grain. I think the analyses given by Dr. Letheby indicate one grain in a gallon as nearly as possible. Many years ago, at the time that I speak of, when I examined the Thames water from Westminster up to the sources, I found nitrates at London in such abundance that on heating the residue red fumes rose up from the crucible. Many years before that it was noticed by Dr. Lambe, and given in a parliamentary

Dr. R. A. Smith

2 April 1868.

report of the time. His analyses, however, generally do not seem correct. Five or six years after my first inquiry I think it was, on examining the waters of the Thames when they had become so offensive that measures were taken to disinfect them, the nitrates had nearly or wholly disappeared. That was the case with the water opposite Westminster. The putrefaction had superseded the wholesome oxidation of the nitrogen. The formation of nitrates is the safeguard of our towns. Without this process of the formation of nitrogen we should be living upon a bed of corruption; still, I certainly should prefer them not to exist in water. By going higher up the Thames we should no doubt get rid of a great many of them. But we might be asked this question, When are we to fear them? We are to fear them when we are not sure of the extent to which the organic matter will be supplied for their formation. In wells, therefore, when we do not know the source of the water, we must fear them; and small supplies of nitrates in a well near a house indicate sewage which has overflowed, and if nitrates are found there I think attention ought to be paid at once to the matter, and the attention should not cease until the nitrates are removed.

7248. They are there because the water could not get them from any other source than sewage, as rivers can?—Just so; so that we have no idea at what point the passage of sewage matter into a well will cease in that case, and therefore, whenever nitrates are found in a well, I recommend people to remove the cause. In deep wells they remain pretty constant, I believe, and we know their limit, so that we have not the same fear then. In river water which is to be filtered we require to be constantly watchful when nitrates appear, lest the organic substances should escape before being converted into nitrates. That, I think, is important. We must fear them also when they have a decided taste, and at a point which medical men may consider to be sufficient to do injury; but the latter point, I believe, has not yet been ascertained. They are often found near graveyards in enormously large quantities, so much so as to affect the taste strongly. It is a curious fact that many of those graveyard wells are rather popular, and the taste does not seem to frighten a large class of people.

7249. You take the presence of nitrates to indicate the possibility of a dangerous origin?—Yes.

7250. Not that they are in all cases to be referred to that origin, but that they are to be referred to other sources besides sewage?—I think the other source, however, is not of very great consequence. I believe all the great sources of water which are likely to be used for London or large cities will have no nitrates, or only very little, and the nitrates that do appear lower down the Thames may be considered as arising from organic substances still imperfectly oxidised, and are therefore so far objectionable.

7251. At the same time do I correctly understand you to say that sewage contamination may take place to a great extent, and yet the water may not show the presence of nitrates?—Yes; the nitrates may be completely removed, although, as a rule, they are only partially removed.

7252. We know that in some rivers and in some lakes nitrates are almost altogether absent, and yet you can hardly suppose but that water flowing into rivers through populous districts, or water supplied to lakes from hard rock surfaces where there is a certain amount of sewage from animals or from a scanty population, must contain a certain amount of sewage matter which may have been got rid of in other forms than that of nitrates?—Yes. If there is a great deal of sewage matter the nitrates, it seems to me, do not appear; putrefaction takes place and oxidation, and the organic matter goes off in the gases of putrefaction, and vegetation takes away the nitrates; there may be another mode of taking the oxygen from the nitrates, but I have only observed those two methods.

7253. In most cases where there is danger to be apprehended from the presence of nitrates have you not been able to detect the presence of chlorides?—Always. Whenever chlorine is high in the water it is necessary to look for nitrates derived from sewage, and, as a rule, it is so constant that there is scarcely any exception. When we find much more than the average quantity of chlorine in a well water, nitrates are found also, and if the water in a district is pretty well known, that is to say, if the amount of chlorine in water from any district is pretty well known, and a specimen of that water should indicate rather more chlorides than usual, you may conclude with almost certainty that it is from sewage.

7254. Can you tell us whether the quantity of organic matter in the water at Manchester varies very much at different periods of the year?—I have not made very many experiments lately upon the water at Manchester, but it certainly varies in colour. I have not, however, been able to say whether it was from what may be called the regular supply, or the supply that is going to be the regular one, on account of the operations going on at the works. They have been doing a good deal of work I understand at the reservoir lately.

7255. Then you do not apprehend any danger from the presence of the organic matter from peaty land in water for drinking purposes?—I have not the slightest fear of any other evil arising from that organic matter beyond what was mentioned. The only point, I think, that requires much attention, with reference to purely peaty matter, is the bitter taste which I think is important to attend to, and the appearance.

7256. Would it be likely to become either deposited or oxidised in a long flow, such as would be the case from Wales or from Cumberland?—I believe it would be completely oxidised either in the long flow or in large reservoirs. But I mention that because I think it is a point which has not received any attention, and it requires a little more attention than I have given it. Probably any new supply would require to have a considerable number of experiments made upon it. All peaty matter may not be removable by oxidation. I think it would be safe, but in such an undertaking we must take nothing for granted.

7257. Would it at all affect the aeration of the water by the time it reached London?—Oxygen is restored rapidly by absorption from the air, if time and surface are sufficient. I do not know very well the waters of Cader Idris or Plinlimmon. I know those of Bala Lake, which I examined at one time when Mr. Rawlinson thought of taking it for the supply of Liverpool, but those were rather brown. Perhaps the Bala water as it exists in the lake would be rather brown for the London people, but it would purify greatly.

7258. Are the Manchester waters and the Loch Katrine waters, as supplied to Glasgow, well aerated?—Yes, they are very well aerated. I do not think they are so bright as the chalk waters, but I believe Glasgow water is always free from colour; Manchester water varies, although there are portions of the Manchester district which give almost absolutely pure water. Dr. Penny found 33·6 per cent. of oxygen in the absorbed air of Loch Katrine water, and found above 27 in Manchester.

7259. In selecting a water for drinking purposes, what qualities should you consider the most desirable to look for, apart from other considerations and other purposes in the use of water?—So far as taste is concerned, I must say that I have no objection to a hard water, and, taking the opinion of other persons and the public generally, I should think that, as a rule, water with a little lime in it was rather liked; but then I consider that very little custom makes us extremely fond of the mountain water, and in an abstract point of view, without considering opinions at all, I should say that the mountain water was the best, simply because there is less extraneous matter in it. We like to drink pure water and any other matter which we wish to take besides water we can add according to our pleasure; it is better not to be compelled to add it in every draught of water, so that abstractly I should be in favour of the mountain water.

7260. Have you been able to form any opinion as to the effect upon health of the use of soft water or hard water?—I do not think there is good evidence upon that point. I have heard of horses losing their appearance when they used hard water, and of persons of my own acquaintance who got indigestion by coming into hard water districts; but then I must say that those cases are somewhat balanced by people being rather disagreeably affected on going to soft water districts, and especially some of the hilly districts of the north.

7261. That depends a good deal, I presume, upon the previous habits of people?—Yes. I do not think that there is a great deal of evidence on either point. I do not think it is fair, in fact, to take the appearance of the population as any criterion. If we did so, we might find some arguments in favour of soft water. I should think that the tallest people in Great Britain are to be met with in soft water districts; for instance, in Cumberland, and probably in Aberdeen. I may say that the tallest people I have seen in Great Britain are in Aberdeen, which is a very soft water district.

7262. (*Sir R. Phillips.*) Are they the most muscular?—They are powerful people. At the same time if we take the death-rates from the Registrar General's reports, we find that the smallest number of deaths occur upon the other side of Scotland, in the western district, where also there is soft water; perhaps that shows that the water has nothing to do with the matter.

7263. (*Mr. Prestwich.*) Nineteen-twentieths of the population of Europe use hard water, do they not?—I suppose they do. The effect is a point about which it would be very interesting to get more information, but it is complicated with questions regarding climate; in nearly all cases the climate of soft water districts is different from the climate of hard water districts.

7264. Are not soft water districts generally mountain districts where they have the purest air as well as pure water?—Yes. I believe, however, it is quite possible for the blood to take up matter which is inorganic, dissolved in water. A common hen, for example, takes up lime in great quantities whenever it requires matter to form its shell; this is an argument to show that food does not require to be supplied in combination with organic matter, but it may be taken up in a purely inorganic form; and Liebig, in his lectures, told us of children who had not been supplied with sufficient phosphates or lime in their food, and who got an intense craving for chalk, as he called it, and picked it from the mortar from the walls. However, I think the food that we do take supplies generally as much lime as we want. I should like to say a word or two about some other salts, if I may be allowed to do so. The chloride test must be used with great care, but the presence of common salt or chlorides is a proof of sewage from animals rather than from vegetables, if we may use the term sewage from vegetables, meaning decomposition of organic matter in and on the ground. But there is another point also to be considered, namely, the sulphates. The sulphur in the albumen oxidises, and it forms sulphuric acid which again, combined with potash as sulphate of potash generally comes from sewage matter, or it may be converted into sulphate of soda, and the potash retained in the soil; silica comes also in sewage. In examining the Thames after the sewage goes into it, the amount of animalcules containing silica, or diatoms with a silicious covering, is enormous. I consider that all the silica from the bread used comes out in the form of those animals; they may be got in millions from one bottle of water if the putrefaction is not very strong. If the putrefaction is, however, as it has been often in the Thames, even those lower forms of life are destroyed, and they do not appear at all. In my early examination of the Thames water I found millions, as I said, but in my later examination, when the Thames was very bad, I did not find them. Those nitrates and sulphates and common salt together form a considerable addition to the total amount of impurity existing in the Thames water when it arrives far down; so that instead of, as at the very beginning, having the hardness and the inorganic matter exactly the same or nearly the same, about 15 to 16 grains in a gallon, we have three or four additional grains caused by those alkaline salts. This increases as we go down. I found at the same time that a very small amount of common salt as well as of nitrates had an effect in diminishing the flavour of water, although I forget the exact amount. The sulphates also affect the taste, but in a very much less degree. However, taking the three together, I consider that there is a perceptible inferiority of taste caused by salts alone in the water low down the Thames compared with the water very high up, or we will say above Pangbourne to an uncertain point, and especially when we go to the sources. When those salts amount to three or four grains they must not be quite despised; they must weigh something in the appreciation of the water as a source of supply to a town. In taking water from the hills it might be necessary to remove the colour by filtration. I have never seen the water from the district proposed by Mr. Bateman, but it might be necessary to remove the colour, and the question would be whether that could be done by natural oxidation, by storage, by running, or by filtration. I have tried many experiments upon filtering, and found that an inquiry was very much wanted as to the best mode of filtering. The animal charcoal which I used completely took out the colour, but I do not know how long it would last; it seems to have a limit rather too early approached. But I tried also at one time a filter made by Mr. Spencer, of magnetic oxide of iron, which removed the least trace of colour from the peat water in a very remarkable degree. It is some eight or ten years since I used it. I do not know whether he can make the filters now with the same degree of perfection which he had attained when he made that one. Those which I examined afterwards did not seem to me to be quite so good, but if he can make them as they were made originally, he could manage to take all the colour out of any hill water, and therefore that objection, I think, would be removed.

7265. Could that be applied on a large scale?—I do not know. I only mention the experiment that I made at the time. I could not exhaust the filter, and it seemed to me an important subject for further inquiry.

7266. Do you consider that there is anything to fear from the action of soft water upon lead?—There is something to fear, that is to say, there is a great deal of caution required. There is not so much to fear that we should be prevented from using soft water simply on that account; but I think it is important, when soft water is used, that there should be no lead cisterns whatever employed, and that the lead pipes should be as short as possible. There has been frequent occasion in Manchester to remark that lead was present in the water; it has been believed to do injury in a number of cases, and it has been necessary in some cases at least to shorten the pipes very considerably.

7267. (*Chairman.*) It is stated, with respect to the Loch Katrine water, that leaden pipes and cisterns very soon become coated with a substance which prevents all action of soft water upon the lead?—That is so stated. I do not find that the action ceases entirely at Manchester. I think the only mode which they have been able to find of getting rid of it has been by shortening the pipes. I have sometimes thought that in peaty water the peculiar acid which I mentioned may have had to do with the objection, but I have not quite proved it. I may mention that I was told lately that in France they have made earthenware pipes and joined them together with a cement which will stand 150 feet of pressure. I have not been able to see them myself, but if that is the case the question of lead may be put aside entirely.

7268. (*Mr. Prestwich.*) Have any instances come to your knowledge of any injurious effect from the presence of lead in the Manchester water?—There

Dr. R. A. Smith.
2 April 1868.

have been several instances where medical men have believed injurious effects to have been caused by the lead, and in several cases where there have been lead cisterns the effect has been very decided indeed; but there have been also several where it has been believed that the lead poisoning had its origin from the pipes alone—enough, at least, to render great caution necessary.

The witness withdrew.

J. Heron, Esq.

JOSEPH HERON, Esq., examined.

7269. (*Chairman.*) You are town clerk of Manchester, are you not?—Yes, I am town clerk of Manchester, and have been town clerk since the establishment of the corporation in 1839.

7270. When you first became town clerk of Manchester, I believe the town was supplied by private companies with gas and with water?—Not with gas. As far as regards the water, which was very bad in quality and very limited in quantity, it was supplied by an old company called the Manchester and Salford Waterworks Company. In 1845 the attention of the corporation was more especially directed to this subject; we were in a most lamentable condition, and it was quite clear that some complete change was necessary. Perhaps I may be allowed to state that about that time the second report of the Health of Towns Commission was published—a commission over which the Duke of Buccleuch presided—and which I have no doubt is familiar to this Commission, for in that report it seems to me the subject is almost exhausted; we found it stated that "the "importance of an ample supply of good water, "accessible at a price within the reach of the poorer "classes of society, and in far greater quantities than "have hitherto been furnished, is a subject worthy "of the greatest attention."

7271. Will you tell us the state of things in 1845, which you describe as being so bad that it was absolutely necessary for the corporation to devise some other mode of supplying the town with water. Did that arise from the large increase of population mastering the capacity of the private company's works, or was it from any other cause in reference to the quality of the water?—It really arose from the fact that the works were totally insufficient in every possible respect to supply water for the population that then and for many years past had existed.

7272. Where did they get their supply from?—There were only two small reservoirs, called the Gorton Reservoirs, situate about three or four miles from Manchester, the water supplying which was gathered from the adjoining district, which was to a great extent agricultural land, but at the same time mixed with a considerable quantity of most objectionable sewage, so that the water was both very deficient in quantity and excessively bad in quality. I think the utmost extent was from 3,000,000 to 4,000,000 gallons a day.

7273. What was the rate charged for the water of the quality which you describe under the old system?—I have not got that information.

7274. I presume they were supplying under an Act of Parliament?—Yes, under an old Act of Parliament.

7275. At all events, the quantity of water was insufficient for the supply of Manchester, and the quality was such as to render it absolutely necessary to seek for fresh gathering ground?—Yes, certainly. The price was very high, and it was supplied upon the intermittent system, and the quantity supplied was very deficient.

7276. Will you state the steps which were taken by the corporation in 1845, to secure a more efficient and a better supply of water?—I was about to state that we find these recommendations incorporated in the report of the commission of the Duke of Buccleuch, and that we sought to carry them out by an Act which we shortly afterwards obtained from Parliament. The report states: "It appears to be generally admitted "by witnesses examined before us, who, being them-"selves connected with existing water companies, "have had every opportunity of observing the effect "of the opposing interests of the companies and their "customers, that a copious supply of pure water cannot "be secured to the poorer classes of the community, "unless the duty of providing it is placed under the "management of some independent body. It should "be the duty of the local administrative body not only "to secure a sufficient supply for all the inhabitants, "but, by contracting with or purchasing it of the water "companies, to ensure its regular distribution at a "fair remunerating price." Another recommendation was—"With the view of ensuring a sufficient supply "and proper distribution of water to all classes, we "recommend that it be rendered imperative on the "local administrative body charged with the manage-"ment of the sewerage and drainage to procure a "supply of water in sufficient quantities not only "for the domestic wants of the inhabitants, but also "for cleansing the streets, scouring the sewers and "drains, and the extinction of fire. For this pur-"pose we recommend that the said body have power "to contract with companies, or other parties, or "make other necessary arrangements." A further "recommendation was—"We recommend that as "soon as pipes are laid down, and a supply of "water can be afforded to the inhabitants, all dwell-"ing houses capable of benefiting by such supply "be rated in the same way as for sewerage and "other local purposes, and the owners of small tene-"ments to be made liable to pay the rates for water as "we have already recommended in respect to drain-"age." The corporation at that time felt so satisfied that it was desirable to carry out those recommendations within the city of Manchester, that we determined to go to Parliament to take power to purchase the works of the existing company, and to go for a large scheme which we believed would be sufficient for our present and prospective wants. But we determined also to go beyond those recommendations, because we determined, believing that it was only right and just, to introduce the principle of a public rate, and I believe it was the first time that the application was ever made to Parliament to obtain power to levy, in addition to a compulsory domestic water rate, a compulsory public rate, payable in respect of all property of every description within the city. We applied to Parliament in 1847, and then and by subsequent Acts obtained power to carry out a scheme which is not yet, I am sorry to say, completed. In 1848 we went for a second Act, which was simply to enlarge the scheme which was proposed by the Act of 1847, and since then we have had to go for other Acts of Parliament to obtain additional power both with regard to the scheme itself, and also for carrying out in detail works within the city and the adjoining districts which we supply.

7277. (*Sir B. Phillips.*) By your Acts of Parliament you have the power of levying two rates, that is, a public or general rate and a domestic rate?—Yes.

7278. (*Chairman.*) Will you give us the substance of the section of your Act which enables you to levy a rate?—By a clause in the Act of 1847, the corporation are authorized and required to estimate and fix the amount of money that will be annually required to meet the expenditure in connexion with the distribution of water; to make, in fact, an estimate. In making out that estimate we have to give credit for all the amounts that we shall receive for water supplied beyond the limits of the city, within which alone the compulsory rates extend, either for domestic purposes or for trading purposes, as well as credit for all the money that we receive within the city for trading purposes, that is to say, for water that is voluntarily taken for trading purposes.

7279. Do you publish this annual estimate?—Yes, annually.

7280. Can you hand one of them in?—Yes, I will hand it in. (*The witness delivered in the same; vide Appendix.*) Then we are authorized, in order to raise a sum of money sufficient to defray the costs, charges, and expenses of supplying the borough with water, to make two rates—first, a domestic rate to be levied upon the occupiers of all dwelling houses within the city, and, secondly, a public rate to be levied upon the occupiers or owners, as the case may be, of all property of every description within the city, including dwelling houses. The public rate ought in fact to have come first in order, but it is second in the Act of Parliament.

7281. The public rate is upon all rateable property, is it not?—Yes, upon all rateable property within the city.

7282. And you have a special rate called a domestic rate?—Yes, upon all dwelling houses within the city.

7283. Now will you give us the amount, first, of the public rate which is applicable to all rateable property, and, secondly, the domestic rate?—The public rate is and has been for many years past 3*d.* in the pound, and the domestic rate is 9*d.* in the pound. It is upon the assessable value of the property in both cases, so that the 9*d.* and the 3*d.* together might be said to represent something like 10½*d.* in the pound on the rateable value, one-sixth taken off being the gross rental in order to obtain the rateable value.

7284. On the rateable value it is 1*s.*?—Yes on the rateable value it is 1*s.*, but on the gross rental, which is the usual mode of obtaining the domestic rate or rental for the supply of water, it would represent 10½*d.*

7285. But it would not be 1*s.* upon all the property in Manchester?—No.

7286. The domestic rate applies simply to dwelling houses, and you have a 3*d.* public rate which does not apply to dwelling houses?—Exactly, the 3*d.* in the pound is payable by all property; of course for that 3*d.* in the pound it will be understood no water is supplied; they simply pay 3*d.* in the pound as a contribution for the advantages which are secured to the whole community as well as for their protection in case of fire, for cleansing streets, flushing sewers, and in any other way. For the advantages, which one can easily understand are secured by an abundant supply of water, property pays that 3*d.* in the pound.

7287. Threepence in the pound is in fact what may be called the borough rate, for the supply of water for municipal purposes, for extinguishing fires, and cleansing streets, and so on?—Yes, and the general benefit in fact which is secured to the district by providing an ample supply of water.

7288. Then the 9*d.* rate on domestic dwellings is in point of fact a rate for the consumption of water?—For the domestic supply.

7289. And the rateable property would indicate the average amount of water consumed, whether you have a rate of 9*d.* in the pound upon 100*l.* rateable property, or 9*d.* in the pound upon 50*l.* rateable property?—Yes.

7290. It is assumed that a 50*l.* house would use half the quantity of water?—They pay half; probably they might consume a great deal more, but that is how the amount payable is ascertained.

7291. Can you tell us the result, first, of the public rate?—I have an estimate for the last year. On the one side we have the estimated expenditure which together amounts to 120,858*l.* 11*s.* 2*d.* That was the estimated expenditure, including as the main item the interest upon our borrowed capital, which is 74,762*l.* 18*s.* 3*d.*, the borrowed capital at the present time being 1,770,477*l.* 10*s.* 5*d.* Our total expenditure in the year is estimated to be 120,858*l.* 11*s.* 2*d.*

7292. That 120,000*l.* a year not only includes interest on the borrowed capital of 1,770,000*l.*, but also all the working expenses?—It does.

7293. Does it include ordinary repairs?—Yes. I wish to state it shortly, but I have got the items; they are very few; there is a sinking fund account, amounting to 12,566*l.*

7294. How do you spend that sinking fund?—In the first instance, by the earlier Acts of Parliament no sinking fund was required. Subsequently, by a clause in the Act of 1854, Lord Redesdale insisted upon our providing a sinking fund, but consented to a moderate sinking fund of 1 per cent. for a number of years, and after 20 years to be increased to 1½ per cent. The corporation desire to extend the repayment over as long a period as possible, for it will be posterity that will get the benefit of this enormous expenditure, and I have always contended that in those great works, which really are for the benefit of posterity quite as much as for the benefit of the present generation, it is only just to spread the expense over the longest possible period, and that to attempt the repayment in 20 years would be a great grievance upon the present ratepayers.

7295. Then this 12,000*l.* a year will be equal to the redemption of that sum at what rate of interest?—The rate of interest upon the whole capital, notwithstanding the times that we have recently passed through, is, I think, equal to about 4 and a fraction per cent. Our rate of interest for a long time was very little over 4 per cent. All the loans falling due during the past year have either been renewed or the amount borrowed on favourable terms, and the average rate of interest upon the present debt, notwithstanding the late monetary panic, does not exceed 4*l.* 3*s.* 4*d.* per cent.

7296. Do you borrow your money on bonds, or how do you raise it?—We have power to borrow it on bonds and mortgages, we have power to raise it upon annuities, and we have power to issue 4 per cent. annuities in perpetuity. We have also power to borrow it on life annuities, and we exercise, as far as we can, all those powers. We have borrowed, I think, 150,000*l.* or 200,000*l.* on perpetual 4 per cent. annuities, and we should be very glad to borrow 1,000,000*l.* if we could upon those terms, so as to have a fixed debt which we could always reduce by the application of our sinking fund, by going into the market if the case arose.

7297. Have you borrowed any money on bonds or mortgages of the rates? Have you power to give the water rate as a security?—Yes, the Act of Parliament gives the whole property of the corporation practically as security for the money that is borrowed.

7298. Then you borrow under the seal of the corporation proper?—Yes.

7299. And not of the water company?—No, certainly not.

7300. Have you any bonds that you issue which are transferable?—Not except in the ordinary way by assignment; it is in the ordinary way in mortgages as well as in annuities.

7301. I suppose you have not many such bonds out; I draw a distinction between ordinary mortgages upon the rates and bonds which are negociable?—We have no bonds at all; ours are all mortgages of the rates or perpetual annuities, which are issued in a different form, but in the form prescribed by the Act; but both the mortgages and the annuities have to be assigned in the ordinary way when they pass from one person to another.

7302. And registered?—Yes, and registered.

7303. And you have had no difficulty in borrowing your funds under this special Act of Parliament, giving as security not only the rate of the water company, but, I suppose, the rate of the gas company, or the property belonging to the corporation?—Yes, the security is the water rate and the borough rate, and that practically includes all the property which the corporation possess. Generally speaking the mortgage is made upon the borough rate.

7304. Has the corporation used as an auxiliary aid the gas profits?—We did for a certain limited period.

7305. I mean the property of the gas company which you have power to rate, and the profits which would arise from the manufacture of gas?—Many years ago. We got power in one of our Acts to apply, if the corporation thought fit, any amount not ex-

J. Heron, Esq.
2 April 1868.

ceeding one moiety of the gas profits in reduction and in aid of the expenses of the waterworks department. I must explain that the gasworks belong to the inhabitants of Manchester, to the ratepayers, and always did, and the gas profits are applicable, under the Act of Parliament, to carry out improvements within and for the benefit of the inhabitants generally of the city.

7306. Would the establishment of waterworks be deemed an improvement under the Act?—It was considered that they would not have been so applicable under the Act without the authority of Parliament, because no doubt the expression in our Act of Parliament referred to physical improvements, that is to say, alterations in streets and other improvements of that kind; but the corporation felt that the improvement which they were going to secure to the city by obtaining an abundant supply of water was really the most valuable improvement that could be suggested, and therefore they applied to Parliament for power to apply, if the corporation thought fit, not exceeding a moiety of the gas profits, in aid of the annual expenses of the waterworks department for 10 years, and for 10 years that application continued; it then ceased, and it has ceased for some years past.

7307. What was that moiety in amount?—It varied from 15,000*l.* to 20,000*l.* and 25,000*l.* a year. Our gas profits I may say, in round numbers, are something like 50,000*l.* to 60,000*l.* a year.

7308. At what rate per 1,000?—I think it is 3*s.* 2*d.* down to 2*s.* 9*d.* per 1,000, according to the quantity that is consumed. It is very low. It is about, I think, the lowest price that is charged. I am not sure whether the Liverpool price is lower.

7309. Are you making it from Newcastle coal?—No, it is chiefly from Cannel coal; we mix other coal with it to a slight extent.

7310. Is it so that you are selling Cannel coal gas for 3*s.* 2*d.* per 1,000?—I think so. It is not solely Cannel coal, but it is Cannel coal mixed with other coal, but, practically, it is called Cannel coal gas.

7311. But it is not pure Cannel coal gas?—No, it is made from Cannel, mixed with other qualities of coal.

7312. You determined at all events to apply a moiety of the gas profits in that way, and Parliament sanctioned the determination, and you did act upon it for 10 years?—Yes, and it has ceased now.

7313. Then, as I understand, the corporation, finding the condition of things in 1845 to be, first, a deficient supply, and, secondly, impure quality, you undertook to supply yourselves with water, and you borrowed money for the purpose of forming works and securing a gathering ground, which has up to this period supplied the town of Manchester with water?—Yes; we commenced and are still carrying out to a certain extent and perfecting the scheme for which powers were then obtained.

7314. I suppose it would have been utterly impossible for anything like the scheme which you have carried out to have been carried out by private persons, and it could only have succeeded by being in the hands of the corporation?—I feel perfectly satisfied that we should never have had such a scheme carried out unless we had undertaken to do it ourselves. We had been for 30 or 40 years in the hands of the water company, and had only been going from bad to worse. Every attempt which they made, and they made several, in Parliament to get power to carry out other schemes failed, and the corporation felt at last that unless they did it for themselves the work would never be carried out. Besides, the expenditure which we undertook was such an expenditure that it is quite certain no private company would ever have dreamt of encountering; nor was it one which they would have been justified in undertaking. A private company could not have acquired the money. If it had asked Parliament they would not have granted them the powers that we obtained; and it is only by the exercise of those powers that we have been enabled to incur such an expenditure, and to supply, as I think I can show you we do supply, water at a very low price to the inhabitants of the city.

7315. I suppose that a company would have been incompetent to carry out the special schemes which you have had in operation in Manchester, that is to say, the levying of a domestic rate and of a lower rate for public or town purposes, unless the power of supply were in the hands of the municipal authorities?—Certainly. I do not suppose such powers would ever be granted.

7316. You are of opinion, are you not, that the supply of water and of gas to any large town should be in the hands of the municipal authorities?—I think the experience that we have had in Manchester has shown to us most clearly that the advantages are very great indeed of the supply being in the hands of the corporation. I could also give you facts in connexion with Liverpool and Manchester, and other places, where the charge to the low class of houses is really extraordinarily low consequent upon the powers which the corporations have obtained.

7317. Are you now supplying water, not only more abundantly, but of a much purer quality, to the inhabitants of Manchester at a less cost than that at which they obtained their supply prior to 1845?—At a very much less cost, and we are giving them an unlimited supply of, as we have always thought, as pure water as is obtainable.

7318. Does that reduction in cost arise from your mode of spreading the burden of supply over all the rateable property as compared with the charge made by a private water company on domestic dwellings only?—In the first place the public rate goes necessarily in reduction of the charge that is to be made for the domestic supply within the city. That is the first important item, and which is obtained by the power which we possess to rate all property within the city. In the second place, no doubt, as the question suggests, we can rate all dwelling houses, whether they take the water or not, (but they do take it, every house within the city takes it,) and this power diminishes considerably the amount which would otherwise have to be charged if you were only supplying, say half or two-thirds or three-fourths of the houses; the cost is the same, the water is there, the water has been obtained, and it costs no more to supply the whole, assuming that we have got the water, which is the fact, than it would to supply three-fourths or one-half of the dwelling-houses.

7318*a*. Was the price at which you should take the grounds and works of the existing company fixed in the Act of Parliament, or was that a matter which you obtained under the Lands Clauses Act?—No, the corporation dealt liberally with the old company. They had spent an enormous amount very unwisely and very unprofitably, but the corporation determined, when it was resolved to undertake the supply of water, to arrange with the old company the price which should be paid for their works. In 1846 or 1847, when we went to Parliament and obtained the Act, we fixed the price which should be paid when we took possession of their property, and we arranged to take possession of their property in 1851. I think the amount that we paid was something like 530,000*l.*

7319. Did you transfer the proprietors from the company to the corporation, or did you borrow independently a sufficient sum to pay off all the shareholders of the old company?—We borrowed the amount which was necessary, and paid the sum in gross which was agreed with the directors and they distributed it amongst their shareholders; and under our Act of Parliament there were clauses for the extinction, in fact, of the company.

7320. Then you utilized their distributing power in the city, and extended it from time to time as matters might require?—Yes, we made use of their pipes and system of distribution to the extent that we could make it available for our works, and we obtained an entirely distinct source of supply, and gave up altogether the water upon which the city had been previously dependent, considering that it was quite

unfit for distribution, and we filled the Gorton reservoirs from our storage reservoirs in the Longdendale Valley.

7321. In seeking for a fresh gathering ground for the supply of the town of Manchester, how did you arrange with the owners of property to keep the water free from that which might contaminate the source of your supply; what was the cost to the corporation for securing and maintaining that gathering ground free from objection?—The small plan which is before you (*see Appendix W.*) will show, on a small scale, our gathering district. We in fact have purchased the whole of the property above the weir which is placed in the river where the quantity of water which we have to send down daily for the supply of the mills passes. There is no drainage into the river above that point; there are no works; there is no source of pollution above that point. I think there is only one set of works existing which we are now purchasing, which are bleaching works, and when we have purchased such works, there will not be any works of any kind within the area of our gathering ground.

7322. What security have you against the erection of works that will contaminate that area?—I fancy the best security is the nature of the ground. It is a mountainous district where there are no dwellings scarcely, or very few; there are scarcely any at all to be seen.

7323. I mean, have you any statutory powers to prevent the erection of works, the opening of lead mines, or any other manufacturing operations that would pollute the water that you gather into your reservoirs?—We have no special powers to prevent any works being established; but there is no chance of any works of any kind being established within our district.

7324. Do I understand you to say that if such an instance should arise in the district you have no power to buy them off?—I do not know that we should really have any such power.

7325. Supposing that the owner of a part of that area chooses to erect a manufactory, the result of which would pollute the water which you are taking into your reservoirs for the purpose of supplying the town of Manchester, have you any power to prevent it by applying for an injunction to restrain him, or must you, finding he is about to erect such a nuisance, buy him out?—There is no doubt that we should have power by injunction to restrain anyone from polluting our source of supply, if such a case did arise; but the fact is that every drop of water nearly that is to be obtained within the district belongs to the corporation, and the land, too, which could be used for works belongs to the corporation. Our reservoirs fill up the valley for something like five or six miles, and on each side are the hills going up somewhat precipitously, forming the gathering ground to the river. There certainly is some meadow and pasture land still left within the valley, belonging either to the Duke of Norfolk, that is, Lord Edward Howard, or to Mr. Tollemache; for, fortunately, we had only to deal with two owners in purchasing the property required for our works. It so happens that one owned the whole of the property on one side of the river, and the other owned the whole of the property on the other side.

7326. But you did not purchase the whole area which you have coloured on the map as your gathering ground?—No, certainly not.

7327. How do you deal with the rights of A. B., whose rights Parliament has not dealt with, and which, therefore, remain intact, supposing he chooses to erect anything on the ground which would interfere with your supply?—We should only have the ordinary power which belongs to all waterworks companies to prevent anybody who cannot show that he had been doing it from a certain time, so as to have obtained the right carrying on any business which would have the effect of polluting our water.

7328. Are you not restricting the rights of property; you have never paid a penny for this right?—I think not; but the fact is that it is a question which I have never had to consider, and there are no such parties in our district. It is not like some districts where you might meet every few yards with property that might appear to be available for business purposes of some kind or other. We have no such sites within the district, and no nuisance of the kind has occurred. There was one property within the district, which was an old printworks, which had not been used for many years, which they said they had once used for dyeworks. It had been unoccupied for very many years; no tenant could be got to take it, for it was too far removed from the markets, and there were many other objections to it as a trading place, but we bought that place. We agreed to buy the property, in order to get rid of the possible chance of somebody taking it merely to try to screw something out of the corporation by saying that they had a right to carry on dyeworks. That is the only place of the kind that I know of.

7329. Have you power under your Act to prevent a man utilizing his freehold as he pleases, supposing that utilization should at all interfere with the quality of your water?—No man can go and establish works in that district to foul our water. We should have power to restrain him by an injunction if he were to attempt to carry on any business, the effect of which would be to render our water impure or unfit for the purposes for which we collect it.

7330. With regard to the supply of Manchester prior to 1845, was it on the intermittent system?—Yes, it was very intermittent and very irregular.

7331. When you established your works did you continue that system, or have you a constant supply in Manchester under high pressure?—From the time that we took possession of the works we have established the system of constant supply. I fancy there was some little delay, perhaps, in carrying it out thoroughly after we took possession, and partly, though not, perhaps, to any great extent, that might have been the result of the general arrrangements which were being carried out for introducing the constant system instead of the intermittent system; but, as a rule, I may say that we have never had the supply upon any other system than the constant system.

7332. Can you tell us what were the difficulties in the first instance in adopting the system of constant supply as compared with the previous system; you purchased the distributing plant of the old company, did you not?—Yes. I am not aware of any difficulties of any kind having occurred.

7333. Did you turn on your water under a given pressure to enable you to extinguish all fires without any alteration being made in the internal fittings of the consumers?—I really can hardly say to what extent some alterations may have been required, but certainly I am not aware, and I have never heard of there having been any difficulties. I do not know that the pipes that were in existence were not found sufficiently strong for the additional pressure they had to bear; and of course, as far as regards the internal arrangements, they would be very simple. I do not know that they would or did require any special change.

7334. Did the result of your new system abolish water cisterns?—There is no doubt that it rendered them unnecessary. I should say that in the small class houses cisterns do not exist; it would be a totally useless and unnecessary expense to go to. I know, as a matter of fact, that they are not put into the small houses.

7335. Do you group a number of houses to one supply, or do you give an independent supply to each house of the poor, for example?—Generally speaking, there is an independent supply to each house. We have 66,907 houses supplied within the city, whilst of 10*l.* rateable value and under, there are 52,737.

7336. (*Sir B. Phillips.*) Is 10*l.* the assessable value?—Yes. We have a certain number of standpipes still left; there are 2,078 stand-pipes, supplying 21,235 tenements, which are chiefly in courts or small streets; they are stand-pipes where the water is constantly on with proper arrangements, so as not

J Heron, Esq.

2 April 1868.

to have unnecessary waste, and to which the tenants of some particular houses have access. I may say that we do not allow any houses to be supplied by means of stand-pipes now, and have not done so for many years; that is to say, no new stand-pipes are erected. For many years the corporation have insisted upon the supply being in each house independently, and the stand-pipes have been diminishing gradually. We shall be very glad to do away with them altogether; they have diminished to the extent of 500 within the last two years.

7337. (*Chairman.*) That is to say, you place a pipe in a house in a convenient spot with a tap?—Yes, and they take the water as they like; it is always on, night and day.

7338. Are those pipes associated with waterclosets, or how do they arrange that?—That is a question which I cannot exactly describe. I am happy to say that in Manchester, as a rule, we have no waterclosets in the small houses.

7339. Have you cesspools?—No, we have no cesspools; the houses have got a privy and a dry ashpit.

7340. Those are emptied from time to time and deodorized by ashes?—Yes, the town performs that duty at a cost of something like 10,000*l.* a year. The privies and ashpits throughout the whole city are emptied by the corporation, and we get rid of the contents as well as we can by sending it into the country, into Lincolnshire or Yorkshire and other places, almost giving it away; but still we do get rid of it, and we get some 8,000*l.* or 9,000*l.* a year towards the expense of nearly 20,000*l.*, which we incur in the operation.

7341. Have you observed by any report from the medical officer, or from your own observation, any improvement in the general health of the inhabitants since the introduction of this pure and abundant water supply, and the adoption of this constant system as compared with the intermittent system, and abolishing all the old mode of storing?—I cannot say that I have observed the change, and of course it is too notorious that the death-rate in Manchester is certainly not at all satisfactory at the present time. In Manchester and in Liverpool, where the supply of water is most abundant, whatever the cause may be, the death-rate is certainly rather high than otherwise, as compared with what it is in many other places. Therefore, as far as that would be a criterion, we cannot boast that there has been any very great improvement. No doubt there must be some.

7342. That may be due, may it not, to imperfect drainage?—Of course it must be due to other causes, because that the benefits from the supply of water have been very great cannot be doubted.

7343. I suppose that for manufacturing purposes the supply of this soft water is a great benefit?—It is an enormous benefit. There are many cases where printers and others pay a very large sum per annum to the corporation for the water in preference to water which might be obtained at a less cost probably, but which is not of the same quality. The income which we derive from the water sold for trading purposes is very large, and it is by that income alone that we are enabled to supply the water at the low price we do for domestic purposes within the city. Perhaps I might just as well state what that is, for I did not finish the information that I was giving with regard to the effect of the two rates. I showed only that the total cost was 120,000*l.* per annum in round numbers. The estimated receipt for trading purposes and for water supplied for domestic purposes beyond the limits of the city is 69,812*l.* a year.

7344. (*Sir B. Phillips.*) Is that over and above the 120,000*l.*?—No; I am giving you the credits. The debit side is 120,000*l.* a year, that is the cost, including everything, in the year for working the waterworks establishment. On the other side we have to estimate our receipts in order to ascertain for what amount we must make the rates; and the receipts on the other side are 76,312*l.*, with sundry other receipts amounting to 3,000*l.*, that being for trade and domestic purposes without the city, making altogether 79,312*l.* Then we have to raise the balance by means of our two rates, one of which at the rate of 3*d.* in the pound on the assessment of 1,438,000*l.* 16*s.*, less one per cent. for loss in collection, it is estimated will raise about 17,797*l.*, and the domestic rate of 9*d.* in the pound on an assessment of 638,508*l.* 10*s.*, it is estimated will raise 21,762*l.*, making together 39,559*l.* 7*s.* 10*d.*, or a total of 120,858*l.* 11*s.* 2*d.*, less 1,987*l.*, which was the balance which we do not provide for in that estimate, but which amount we know, from the experience of past years, will be more than provided by the increased amount received for domestic and trading purposes during the year.

7345. (*Chairman.*) Is your rate pretty uniform from year to year?—Yes; it has remained the same for many years, and I think myself that the probability is that it will continue the same for many years to come, because if we have a balance, which we have had in some years, beyond our expenditure in the receipts, we do not carry it to the credit of the next year, but we pay it in addition to the amount which we have raised expressly towards the sinking fund. Our sinking fund is small, and if we could raise three times the amount, probably in the shape of the sinking fund, without raising or altering the present rates, we should do so, because it is felt that the rate at which we now supply the water is quite as low as anybody has a right to expect.

7346. Then anything plus your expenditure is added to the sinking fund?—Yes, thus reducing the debt; and we always begin the next year without any credit.

7347. (*Colonel Harness.*) How do you fix the charge for water supplied outside the city?—It is fixed by the Act of Parliament, and it is five per cent. upon the rental; that is to say, it cannot exceed five per cent. upon the rental. As a rule it is five per cent. upon the rental of the property to which it is supplied, with the usual limitation that in no case is it to exceed 10*l.* I think it is that as the rule; and then there are the ordinary powers for charging for baths, stabling, and the ordinary powers given to a waterworks company. I may state that the area over which Manchester supplies water is something like 80 square miles. The whole district is in fact dependent upon Manchester for its supply of water.

7348. (*Chairman.*) When you speak of Manchester, do you include Salford and those other places?—Yes, we supply Salford. The whole district, including Salford, is dependent upon Manchester for the supply. We go all round the city. We supply three companies entirely. The corporation of Salford is supplied entirely by Manchester in consideration of an annual charge. We supply Staley Bridge; they are making works for themselves. But we supply the North Cheshire Company, which goes to Bowdon, Stretford, and that district. We supply Tyldesley, which is beyond Manchester five or six miles on the other side towards Worsley, and all the districts round it. We also supply the Dukinfield Company, and we supply Stockport with a portion of their water, and Hyde, besides all the intermediate district.

7349. In the city of Manchester have you not a number of hydrants in different parts for the purpose of suppressing fire in the town?—Yes, the fire arrangements, I believe, are as complete almost as could be desired.

7350. What height can you throw your water from those hydrants?—The height varies; but I may state that the use of engines is a thing not known scarcely, and it is never required to use engines in case of fire.

7351. Are you able to throw your water to the top of those very high manufactories?—Yes, easily; without any difficulty we can throw it over the highest buildings that exist. The corporation not very long ago went to a very large expense in order to secure a better pressure, not only for the extinction of fires, but also for the supply of some of the highest districts. If you look at the little map you will see Godley is shown as one of our reservoirs; it is the first of our service reservoirs on the Manchester side after

oming through the hill, and at a much higher level han Denton, from which the supply had been previously obtained. The corporation expended something like 100,000*l.* to bring a new main from that Godley reservoir into Manchester, by means of which we are able to supply the districts beyond Manchester which I have already referred to, which are at a high level, and also to supply the whole of the high districts within the city itself and the immediate neighbourhood with all the pressure that is desired. This pressure can be obtained throughout the whole city in case of fire.

7352. Do I understand that this new reservoir to which you refer simply gives you a greater head of water and increases your pressure; but is that pressure constantly on in Manchester, or have you some mechanical means of turning it on in case of fire occurring in the district?—It is constantly on in some portions of the district; but there are districts where the Denton pressure is on, and also there are other districts where the Gorton pressure is on ordinarily, but there is no difficulty in case of fire in turning on the largest pressure that we have. We can turn the Godley pressure into those districts by mechanical arrangements which exist, so that in case of fire the highest pressure may, if it is necessary, be obtained. I do not know whether it has been stated before, but the result of the operations of our fire brigade have been most extraordinary. I have here a statement of the annual number of fires that have taken place for many years, the amount of property that has been destroyed, and the amount of property at risk that has been saved; and it is extraordinary how the per-centage of property saved has increased during the last few years and the per-centage of property destroyed decreased.

7353. You mean since you increased your pressure?—Yes, since we got a better pressure. Last year's return shows that 97·5 per cent. of the property at risk was saved, there having been lost only 25,605*l.*, whereas there was 1,019,779*l.* property at risk; and I see that in the previous year there was 90 per cent. saved. In 1866, the year before that, there was 96·7 saved, 96·8 the year before that, 94 the year before that, and so on for many years back; and before that there has been actually only 59 per cent. saved, and 78, 80, 85, and 66, but I believe that the operations of the fire brigade have been in every respect extraordinarily satisfactory to all parties concerned.

7354. Before going into another part of the question, let me ask you whether the corporation annually appoint a committee for the purpose of managing its water supply and gas, or separately?—The waterworks committee is a distinct committee.

7355. (*Sir B. Phillips.*) You mentioned that you had a general rate and a domestic rate. Will you be good enough to tell us in what way manufacturers are supplied by you, is it by an independent rate, or is it by an arrangement?—Manufacturers are supplied at such prices as may be arranged between them and the corporation; but the fact is that the corporation have fixed the rate of charge, beginning at 1,000 gallons and going up to 3,000,000 gallons per quarter, which is published. I cannot state exactly what the price is, but I think it begins at something like 2*s.* per 1,000 gallons, and if they take 3,000,000 gallons quarterly, I know the price is cut down to nearly 3*d.* per 1,000 gallons.

7356. Can you tell us what amount the corporation derive annually from the supply of water for manufacturing purposes?—Yes. I find that the trade rentals within the limits of the city, that is, for water supplied for trade purposes only within the limits of the city, were 35,647*l.*, and beyond the limits of the city, 10,734*l.*, that is, 45,000*l.* a year and upwards. The domestic rentals beyond the city were about 23,430*l.*; so that it is 45,000*l.* and upwards that we receive for water sold for trading purposes.

7357. That amount is produced, is it not, by arrangement with the manufacturers?—That is so.

7358. You have told us that there are something over 50,000 houses at Manchester rated at 10*l.* per house and under; you have necessarily some very small tenements?—Very.

7359. Speaking of small houses, can you tell us what number of houses you have of 5*l.* and under per annum?—The number of assessments at 5*l.* and under is 4,656, and the value is 23,280*l.*

7360. Do the corporation collect the water rate from each of those houses separately, or from the proprietors or landlords?—From the landlords. The landlords are liable, by a special clause, for all property in Manchester let to weekly tenants, whatever the rent may be; but they are liable for all at 10*l.* and under, quite independently of that additional power which we obtained. We found that it was so desirable that where there were weekly tenants constantly changing, the landlord should be made liable, that we got that power in one of our Acts.

7361. Is that merely for weekly tenants?—The landlords are liable under all circumstances for 10*l.* and under, but they are liable also in all cases where the property is let to weekly tenants.

7362. Are we to understand that if a house be let in Manchester, and is rated at 7*l.*, 8*l.*, or 9*l.* per annum, and the tenant in possession refuses to pay the water rate, the corporation can oblige the landlord to pay it?—We should not go to the tenant; we go to the landlord. We have nothing to do with the tenant; we are compounders, that is to say, we go to the landlords. If I were to refer to the clause I could tell you what the amount is that the landlords are entitled to have in reduction, but we can go to the landlord, who is liable; he makes his own agreement with his tenant. We have nothing to do with the tenant at all.

7363. I think I understood you to say that each of those houses is supplied with pipes brought into the house?—To the extent to which I have already stated.

7364. You stated that there were something like 2,000 stand-pipes which had been reduced 500. In all the recently built houses you introduce pipes and taps, do you not?—Yes, there are 31,502 houses which are supplied internally, and externally, by means of stand-pipes, 21,235.

7365. How is the water stored that supplies those pipes?—There is no storage in any case, it is always on. If it is a stand-pipe they have nothing to do but turn the tap, or whatever it may be, and there is the water.

7366. That I suppose comes from the reservoir in the immediate neighbourhood?—No, it comes from the pipes some miles from any reservoir; it supplies the stand-pipes as it supplies the houses, from pipes running through the streets.

7367. (*Colonel Harness.*) Has it ever occurred that the district was without water on account of repairs being done to the pipes in the streets?—Occasionally of course that does occur. I know in my own house, which is in Broughton, the other day for some hours we were without water, but then in the course of a few hours it was on again. That must necessarily arise occasionally; if there is the bursting of a pipe no possible means can prevent the whole district being without water for a limited period.

7368. Except they use the cistern?—Precisely so. A cistern might be useful under such circumstances.

7369. (*Sir B. Phillips.*) For a limited period the whole district would be without supply until the pipe was repaired?—It might; of course the district might be smaller or larger, but I have never heard of any inconvenience arising from it.

7370. (*Mr. Harrison.*) Many of your large houses have cisterns, have they not?—Yes, I scarcely know of any large houses that do not have cisterns to catch the rainwater.

7371. (*Chairman.*) Have you calculated at all the quantity of water per head of the population?—Yes; the estimated consumption per head is 13½ to 14 gallons daily.

7372. Is that apart from the borough consumption, as you may call it, and from the manufacturing consumption?—It is apart from the manufacturing, as that estimated consumption is for domestic purposes only.

J. Heron, Esq.
2 April 1868.

7373. Taking the whole supply of Manchester, both for municipal and manufacturing purposes, and for domestic supply, what is the supply, as spread over the inhabitants, per head?—The total quantity of water distributed now is about 14,000,000 gallons daily. The population is about 650,000, and the estimate for consumption for domestic purposes is 13½ gallons daily, making about 9,500,000 gallons; there is something like 4,500,000, say 5,000,000 gallons supplied for trading purposes, and that would include sanitary purposes.

7374. Taking 13,000,000 gallons for domestic purposes, and then adding the 4,000,000 to 5,000,000 gallons for other purposes, spreading it over the whole that would give the average consumption, per head, at about 22 gallons?—I have no doubt it would be nearly that. I have a statement which I thought might be interesting, showing what the rates are in other places: In Manchester we have the 3*d.* public rate and the 9*d.* domestic rate; in Glasgow they have 1*d.* public rate, and their domestic rate, which is compulsory, is 1*s.*; in Liverpool they have a fixed and unvarying 6*d.* public rate, by Act of Parliament, 3*d.* of which public rate is payable by the owner and 3*d.* is payable by the tenant. The domestic rate, which is not compulsory, is only about 6¾*d.* in Liverpool.

7375. Liverpool supplies itself in the same way as Manchester, does it not?—They have not a compulsory domestic rate. It is voluntary as far as the domestic rate is concerned.

7376. But the waterworks are in the hands of the corporation?—Yes, they are; and in Glasgow they are in the hands of the corporation also, and there it is compulsory, both the public and domestic rate. In Bristol they have no public rate; but in Dublin they have adopted the same principle as in Manchester. They have a 3*d.* public rate, and they have a 1*s.* domestic rate; but there their charge is much higher than Manchester. There is no place but Liverpool that I can see which supplies water for the small class houses as cheaply as we do in Manchester; but in Liverpool the price they charge is extraordinarily low, for they begin at 1*s.* 8*d.* a year for the small houses. I will hand in to the Commission a comparative statement of the charges between Manchester and other places. In the Act of Parliament we got power to charge for all premises if supplied externally, that is to say, by means of stand-pipes, 4*s.* a year—not to be called upon to supply for less than 4*s.* a year; and for all premises supplied internally 5*s.* a year; and that is the rate charged for nearly all houses, we may say, under 10*l.*

The witness delivered in the following table:—

MANCHESTER CORPORATION WATERWORKS.

Charges by various Companies for Water—Public and Domestic.

Name of Town.	Corporation or Company.	Public Rate in the £.	Domestic Rate in the £.	Compulsory or by Agreement.	——
Manchester	Corporation	3*d.*	9*d.*	Compulsory.	
Glasgow	Do.	1*d.*	1*s.*	Do.	
Liverpool	Do.	6*d.* See note A.	6¾*d.* See note B	Compulsory on 10*l.* and under.	
Dublin	Do.	3*d.*	1*s.*	Compulsory.	
Bristol	Company	None	5 °/₀ to 25*l.*, then sliding scale to 2½ °/₀.	By agreement.	
New River Company, London.	Do.	None	Under 200*l.* 4 °/₀ on the annual value, equal to 9¾*d.* in the £; above 200*l.* 3 °/₀ on the annual value, equal to 7½*d.*	Do.	
Birmingham	Do.	None	To 5*l.* per annum 6*s.* per annum from 5*l.* to 7*l.* 10*s.* 8*s.* do. 7*l.* 10*s.* „ 10*l.* 10*s.* 4*d.* do. 10*l.* 0*s.* „ 12*l.* 10*s.* 16*s.* 9*d.* do. 12*l.* 10*s.* „ 15*l.* 24*s.* do. 15*l.* „ 17*l.* 10*s.* 31*s.* do. 17*l.* 10*s.* „ 20*l.* 38*s.* do.	Do.	Houses 10*l.* 8*s.* and above may be farmed by landlord, and 20 °/₀ allowed for a term of years for composition or empties.

A.

The Liverpool Corporation charge the compulsory public rate half to owner and half to tenant as per 25° & 26° Vict., cap. 107, sec. 27, (Liverpool Corporation Waterworks Act, 1862), but in case of cottages let at 10*l.* and under the owner is made liable to the whole rate, one half of which he may charge to the tenant at rent, but the assessment is not to be increased in consequence of such additional charge, and 25 per cent. is to be allowed as composition.—*See sec.* 46.

B.

The domestic rate for property 10*l.* and under is made chargeable to the owner under the provisions of 10 Vict., cap. 17, sec. 72 (the Waterworks Clauses Act, 1847); 25 per cent. also being allowed to the owner as composition.

7377. About 2½ per cent.?—Yes.

7378. (*Mr. Harrison.*) What surplus do you suppose you have beyond your present delivery within the gathering ground that you have?—I am not quite certain what would be the surplus at the present moment; but we have a large surplus, and when the works are completed which we have in progress, and which will be completed before the additional quantity of water will be required, we shall have, as far as we can judge, at least 25,000,000 gallons a day, after providing 14,000,000 gallons a day which goes down the river for the supply of the mills.

7379. Have you no fear at all of any deficiency of supply for Manchester, or for the district that you supply in addition to it?—Certainly not.

7380. You do supply towns at a distance as great as 10 miles, do you not; or what is the most distant place?—Directly we do not go quite so far. Bowden is perhaps the most distant place that is supplied from the Manchester Waterworks; but that is through the intervention of another company, the North Cheshire Waterworks Company; but it is our water that supplies them. It also goes to Alderley, which is supplied through the Stockport Waterworks Company with our water, and is 14 or 15 miles from Manchester.

7381. Would it be a good principle for a company or corporation situated as you are, and being of necessity obliged to undertake very extensive works to supply not only your own town, but an extensive district in connexion with it, say within the same watershed as yourselves?—I think it is decidedly an advantage for any company, situated as we are, to have, provided they have got the water, as large an additional district to supply as possible. The coporation is able to supply a large district beyond the limits of the city, and it is by means of the income which we thereby obtain that we are able to pay our expenses and to keep down our rates within the city.

7382. Have you ever turned your attention to the same principle being carried out upon a much more extended scale than it is at present with regard to other districts in England?—No, I cannot say that I have ever considered the question from that point of view. One can very well see that what has proved advantageous in Manchester in its working would, if the same system were carried out in any other district, have the same result.

7383. Do not you find within your own district that there are many towns not of sufficient magnitude to justify their going to any large expense to get the

best water, who can now be supplied through you much more economically than they otherwise could have been?—No doubt; and I believe that if the corporation of Manchester had not carried out those large works which enable them to supply those small districts, those districts would have been without water. They never could have encountered the expense as well as the difficulty which would have been necessary in order to obtain it.

7384. Does your experience lead you to the conclusion that works carried on by a corporate body are economically done?—I do not see why they should not be carried out quite as economically as under any other system. Certainly, if the duties devolving upon those to whom the works belong are properly performed, one would expect there would be greater regard to economy than under any other arrangement.

7385. Do you find that the gentlemen whom you may appoint as special members of that committee find time to devote to it?—They do certainly give their time in a manner which often surprises me, and I think they sometimes pay more regard to economy in carrying out the works than they would do probably if it was their own business. As far as my experience goes I can certainly bear strong testimony to the time and attention which the members of the corporation pay upon those important committees, both the gas committee and the waterworks committee.

7386. With regard to the economy in the consumption of water or otherwise resulting from constant supply, can you give any opinion upon that subject?—I do not think that my opinion would be of much value. I do not think I can speak with anything like authority. We have fortunately had no experience except of the one system, and we cannot understand at all how any other system can for one instant be put in competition with it. Our impression is that it is decidedly more economical to have a constant supply than an intermittent, and that there is less lost in many ways which I have no doubt will suggest themselves to you.

7387. What powers of supervision have you over the different houses and tenements?—We have most ample powers of every kind both for inspection, to see that the fittings of every description are of a satisfactory character, and also to provide what those fittings shall be. The corporation have the most complete powers. We had to apply several times to Parliament to get amended powers, which we have found necessary. We certainly are not working under the ordinary Waterworks Clauses Act. We have many provisions which I do not think are to be found in that Act of Parliament. We have most ample powers with reference to fittings, and also for the purpose of inspection.

7388. Would not a similar power be a matter of absolute necessity in the case of London being put upon the constant supply system?—I should think it absolutely necessary in any case. I think it is quite right that whoever is supplying water, whether it is a corporation or a company, should have ample power to see that the water is not being improperly wasted.

7389. Do you find any complaints from owners of property of such supervision being at all inquisitorial?—Not at all; I never heard a complaint of the kind, and we have found it to be most necessary; for when we increased the pressure in the way which I have mentioned to the Commission we found our consumption was very rapidly increasing, and that there must be some cause for it, and an extra inspection was immediately ordered, and we found that the fact was that the pressure of the water on the ball taps, the handle of which was not of very strong metal, but rather a pliable metal, had twisted it, so that the ball tap was no longer operating in any way, and that in scores of cases there was a constant running to waste of our water. When that was discovered the corporation took means instantly for supplying ball taps of a different description, which would be strong enough to bear this pressure.

7390. Are the powers which you possess set forth in the different Acts which you from time to time obtained?—Yes, they are. I intended to have brought a printed copy of all the provisions, but I will undertake to send it to the Commission if it be considered as put in. It is printed separately for the information of everybody. I hand in a printed copy of the clauses referred to.

J. Heron, Esq.

2 April 1868.

MANCHESTER CORPORATION WATERWORKS.

EXTRACTS FOM THE WATERWORKS ACTS (AND THE ACTS INCORPORATED THEREWITH) RELATING TO THE MODE OF SUPPLY, PROTECTION OF THE WATER, &c.

Waterworks Act, 1860; 23 *Vict. Cap.* 93.

Regulations for preventing waste of water supplied by the corporation.

CLAUSE 3. For the purpose of preventing the waste, misuse, or undue consumption or contamination of the water of the corporation, the corporation from time to time may prescribe the size, nature, strength, materials, mode of arrangement, and repair of the pipes, valves, cocks, cisterns, water-closets, and other apparatus to be used; and may interdict any arrangement and the use of any pipes, valves, cocks, cisterns, water-closets, and other apparatus which, in their judgment, may tend to any waste, misuse, undue consumption, or contamination.

Conditions of supply.

4. The corporation shall not be bound to supply any water unless the pipes, cocks, cisterns, water-closets, or other apparatus to be used be made of such size, nature, strength, and materials, and be so arranged and repaired, as the corporation from time to time prescribe or approve; and in the event of any dispute as to whether such pipes, cocks, cisters, water-closets, and other apparatus are of such size, nature, strength, and materials as aforesaid, or have been so arranged and repaired as prescribed and approved by the corporation, such dispute shall be settled by two justices, either of the city of Manchester or the county of Lancaster, in the manner provided by "The Railways Clauses Consolidation Act, 1845," with respect to the recovery of damages not specially provided for, and of penalties, and for the determination of any other matter referred to justices.

Repair of pipes, &c. by the corporation.

5. The corporation may, after twenty-four hours' notice, repair or alter any pipe, valve, cock, cistern, water-closet, or other apparatus, of any person supplied by them with water, so as to prevent any waste of water; and the expenses of the repair or alteration, if well and effectually done, shall be repaid to them by the person on whose credit the water is supplied thereto, and may be recovered by them as damages.

Penalty for waste of water by non-repair of pipes, &c.

6. Every person supplied with water by the corporation who wilfully or negligently suffers any pipe, cock, cistern, water-closet, or other apparatus to be so used as that water supplied to him by the corporation is wasted or misused, so as to allow an undue consumption of the water of the corporation, or to allow the return of foul air or other noisome or impure matter into the pipes belonging to the corporation, or connected with the mains or pipes of the corporation, shall for every such offence forfeit to the corporation a sum not exceeding five pounds.

Particulars of penalties shall be published.

7. The corporation shall, from time to time, publish the short particulars of the several offences for which any penalty is imposed by this Act, or "The Waterworks Clauses Act, 1847," or either of them, or by any byelaw of the corporation affecting other persons than the corporation, their officers or servants, and of the amount of every such penalty; and also the size, nature, and strength of the pipes, cocks, and other apparatus to be used within the district which the corporation are empowered to supply with water; and shall cause such particulars to be painted on a board, or printed upon paper and pasted thereon, and shall cause such board to be hung up or affixed on or in some conspicuous part of the Town Hall at Manchester.

Powers to corporation for ascertaining quantity consumed by meter, and for removing meters.

9. The officers of the corporation may enter any house, building, or lands supplied by the corporation by measure, in order to inspect the meters, instruments, fittings, and works for regulating the supply of water, and for the purpose of ascertaining the quantity of water consumed or supplied, and may from time to time enter any house, building, or lands for the purpose of removing or carrying away any meter, instrument, pipes, fittings, or other works belonging to the corporation; and if any person hinder any such officer from entering and making such inspection, or effecting such removal, every person so offending shall for every such offence forfeit to the corporation a sum not exceeding five pounds; provided always, that, except with the consent of a justice, such power of entry shall not be exercised at any hour not authorized by "The Waterworks Clauses Act, 1847."

J. Heron, Esq.

2 April 1868.

Penalty for affixing tubes to pipes of corporation without their consent.

10. It shall not be lawful for any owner or occupier of any house supplied with water by the corporation, without the consent of the corporation, to affix, or permit or suffer to be affixed to any of the mains or other pipes of the corporation, or to any service-pipe of such owner or occupier, any gutta percha or other tubes or pipes for the purpose of washing the windows or fronts of houses or other buildings, or for watering any gardens or the pavements or roads adjacent to such houses or buildings, and any person who shall act contrary to this enactment shall, for every such offence, forfeit to the corporation any sum not exceeding forty shillings.

Waterworks Act, 1863; 26 & 27 *Vict.*

Provision with respect to the illegal use of water.

Clause 41. And whereas by the act of one thousand eight hundred and forty-seven the corporation are empowered to levy within the city of Manchester, from all occupiers of all dwelling-houses, a rate called the domestic water rate, and are compellable in consideration thereof to supply to such dwelling-houses water for the domestic purposes defined in that Act; and by the same Act the corporation are also empowered to demand and receive from the occupiers, and in some cases from the owners, of dwelling-houses within their limits of supply outside the said city, requiring to be supplied with water for domestic purposes as so defined, the several rents in the said Act mentioned: And whereas the water supplied by the corporation for domestic purposes as so defined, is frequently used by manufacturers, dyers, printers, bleachers, brewers, innkeepers, alehouse keepers, beershop keepers, vintners, and other persons for purposes other than those defined by the said Act as domestic purposes, and no sufficient provision exists for the prevention thereof: therefore in any case in which any person receiving from the corporation a supply of water for domestic purposes shall knowingly use, or permit to be used, any of such water for purposes other than domestic purposes, as defined by the said Act, the corporation may, if they think fit, thenceforth refuse to supply water to such person at and for the rates or rents for domestic supply prescribed by the said Act, and such person shall thenceforth in respect of the same premises be entitled to a supply of water only under the provision of the ninety-sixth section of the said Act.

Penalty on interference with valves, &c., of the corporation.

42. Every person who shall wilfully, carelessly, or without due authority from the corporation, in any way interfere with any valve, pipe, lock, cock, or other apparatus or works of the corporation, or with any meter used for registering the quantity of water supplied by the corporation, shall, without prejudice to any other right or remedy for the protection of the corporation, or the punishment of such offender, be liable to a penalty for every such offence not exceeding five pounds.

Water may be cut off in certain cases.

43. If any person supplied with water by the corporation wrongfully do, or cause or permit to be done, anything in contravention of any of the provisions of the Waterworks Acts, or of the incorporated Acts, or of this Act respectively, or wrongfully fail to do anything which under any of those provisions ought to be done for the prevention of the waste, misuse, undue consumption or contamination of the water of the corporation, the corporation may cut off any of the pipes by or through which water is supplied by them to him or for his use, and may cease to supply him with water so long as the cause of injury remains or is not remedied, and may also recover from him the amount of any loss, damage, or injury sustained by them by or in consequence of any such act or failure by action at law, in any court of competent jurisdiction, including any county court, or other court having cognizance of any cause of action of like amount.

Penalty for waste of water by non-repair of pipes, &c.

44. If any person supplied with water by the corporation shall wrongfully cause or suffer any pipe, valve, cock, cistern, bath, soil-pan, watercloset, or other apparatus or receptacle to be out of repair, or to be so used or contrived as that the water supplied to him by the corporation is or is likely to be wasted, misused, unduly consumed, or contaminated, or as to occasion or allow the return of foul air, or other noisome or impure matter into any pipe belonging to or connected with the pipes of the corporation, such person shall, for every such offence, forfeit to the corporation a sum not exceeding five pounds, and shall forthwith remove, replace, or alter, or permit to be removed, replaced, or altered, any such pipe, valve, cock, cistern, bath, soil-pan, watercloset, or other apparatus or receptacle, to the satisfaction of the corporation or their duly-authorised officer.

Penalty on wrongful use of water.

45. Every person who, not having agreed to be supplied with water by the corporation, shall wrongfully take or use any water from any reservoir, watercourse, conduit, or pipe belonging to the corporation, or from any pipe leading to or from any such reservoir, watercourse, conduit, or pipe, or from any cistern, fountain, or other like place containing water belonging to or supplied by the corporation, shall for every such offence forfeit to the corporation a sum not exceeding five pounds, and every person who, being rightfully entitled to make use of the water of the corporation for any purpose, shall take or use any water from any such reservoir, watercourse, conduit, or pipe, or from any such pipe, cistern, fountain, or other like place for any purpose other than the purpose for which he is so entitled to be supplied, shall for every such offence forfeit to the corporation a sum not exceeding five pounds, and in any of the cases aforesaid the corporation shall be entitled, in addition, to recover from any such person the amount of any loss, damage, or injury sustained by them by or in consequence of any such wrongful acts by action at law, in any court of competent jurisdiction, including any county court or other court having cognizance of any cause of action of like amount.

46. Any person who shall, without the knowledge or consent of the corporation, affix, extend, or enlarge any pipe, or use any other means or device for the purpose of supplying any other person or tenement with water from the works of the corporation, shall forfeit and pay a sum not exceeding five pounds, and a further sum not exceeding forty shillings, for every day during which such offence shall be continued.

Waterworks Clauses Act, 1847; 10 *Vict. Cap.* 17.

Clause 57. The surveyor, or any other person acting under the authority of the undertakers, may, between the hours of nine of the clock in the forenoon and four of the clock in the afternoon, enter into any house or premises supplied with water by virtue of this or the special Act, in order to examine if there be any waste or misuse of such water; and if such surveyor or other person at any such time be refused admittance into such dwelling-house or premises for the purpose aforesaid, or be prevented from making such examination as aforesaid, the undertakers may turn off the water supplied by them from such house or other premises.

58. Every owner or occupier of any tenement supplied with water under this or the special Act, who shall supply to any other person, or wilfully permit him to take any such water from any cistern or pipe in such tenement, unless for the purpose of extinguishing any fire, or unless he be a person supplied with water by the undertakers, and the pipes belonging to him be, without his default, out of repair, shall forfeit to the undertakers, for every such offence, a sum not exceeding five pounds.

59. Every person who, not having agreed to be supplied with water by the undertakers, shall take any water from any reservoir, watercourse, or conduit belonging to the undertakers, or any pipe leading to any such reservoir, watercourse, or conduit, or from any cistern, or other like place containing water belonging to the undertakers, other than such as may have been provided for the gratuitous use of the public, shall forfeit to the undertakers, for every such offence, a sum not exceeding ten pounds.

60. Every person who shall wilfully or carelessly break, injure, or open any lock, cock, valve, pipe, work, or engine belonging to the undertakers, or shall flush or draw off the water from the reservoirs or other works of the undertakers, or shall do any other wilful act whereby such water shall be wasted, shall forfeit to the undertakers, for every such offence, a sum not exceeding five pounds.

7391. Had you an opposition originally to the power of levying an unlimited rate?—We had no opposition at all. It may have been that it was scarcely understood. It is quite certain that no such power would again be granted by Parliament as we have in this Act. When Glasgow proposed to follow our example there was an opposition, and they were limited to a public rate of, I think, not more than a penny in the pound. We can levy any amount of public rate we please; there is no limit either on the public or the domestic rate, nor is there anything in the Act of Parliament to fix the proportions of the two rates. At the same time the corporation have tried to fix it upon a principle which is satisfactory to the inhabitants, and I may say, from my own knowledge and experience, that I believe there is no rate paid in Manchester so willingly and so cheerfully as the 3*d.* public rate, for which a great number of the largest ratepayers get nothing except the advantage of improving the district.

7392. (*Chairman.*) They get protection from fire; do they not?—Yes, but they get that without it in many other places; they always have protection against fire wherever waterworks exist; they have

right to have water without charge in case of fire. In Manchester of course they have that advantage amongst others, but still the public rate was a new charge.

7393. (*Mr. Harrison.*) Do you find that the fact of your having that unlimited power of rating has enabled you to borrow your money more cheaply than you otherwise would have done?—That has occasionally been made use of as an argument to show the satisfactory character of the security, but I do not see that there is practically any very great value in it in that respect, because any corporation that has power to borrow, and to borrow upon the security of their borough rate or their water rate, necessarily can borrow to any extent required; there is no limit to the borough rate, even if we had not that special power for making a public rate, but only power to borrow on our borough rate. We have the power to make a borough rate to any extent which is required to meet the requirements of the corporation.

7394. You are acquainted with all the district of Lancashire; could you mention the names of the chief towns which, like Manchester, have taken the waterworks into the hands of the corporation?—I find that the supply of water is in the hands of the corporations in Ashton-under-Lyne, Bolton, Bradford, Halifax, Leeds, Liverpool, Oldham, Preston, Rochdale, and Stayley Bridge.

7395. I gather from your own experience in the case of Manchester that you are thoroughly convinced of the advisability of all corporations undertaking the water supply themselves?—I am perfectly convinced of it. I think the reasons are unanswerable, and one of the strongest reasons is, first of all, that they may obtain power to rate the inhabitants, which I do not suppose would be granted to any private company; they get power to rate everybody whether they take water or not, so as to spread the expense over the largest possible area, and they get that which after all is one of the objects of greatest importance, and I think so reasonable and so just—they get power to tax the whole of the property within the area with a public rate, which is in reduction of the expense of distributing water amongst the domestic consumers.

7396. In the case of those towns and districts which you supply beyond the limits of your own borough, are you by your Act of Parliament limited with respect to the amount which you charge them?—Yes, certainly; we supply outside the city precisely upon the same terms and in the same way as any private company would do; we are limited entirely by the clauses in our Act, and beyond the limits of the city we have just the ordinary powers which belong to any ordinary waterworks company.

7397. The rate which you charge beyond the limits of your borough is, I presume, higher than what it is in your borough?—Certainly; but there is not so very great a difference as may be supposed. As I said, the actual charge in the borough is practically 10½*d.* upon the gross assessment, and the charge outside the borough is always estimated upon the gross rental. Under our Waterworks Act it is five per cent. upon gross rental that we are authorized to charge; therefore the charge outside is as 1*s.* in the pound to 10½*d.* in the pound inside, that is, including the 3*d.* public rate and the 9*d.* domestic rate. But then in addition there is a power to charge which we have never exercised, but which I think is exercised by most companies, for baths and a variety of other extra charges which we have never made; we have been content with the five per cent. hitherto.

7398. Are you under an obligation to supply those districts?—No, none whatever, except in one case. I think in the case of Salford it is under an arrangement made by Act of Parliament but in the other districts arrangements have been voluntarily entered into with the corporation to supply them; they are not under any obligation.

7399. Would you have thought it objectionable if in your case, when you were going for such large powers, you had been laid under any obligation to supply particular districts, assuming always that there was an abundance of water to do it?—I should have thought it anything but an undesirable arrangement, because, of course, if we had been put under an obligation to supply them we should have been perfectly justified in saying that they should have been put also under an obligation to come to us as customers, and it would have been a great advantage to us to have known that we were not only going to get certainly the money which would be obtained within the area of the corporation, but that we were also going to secure, as a matter of equal certainty, customers outside. The expense of getting the water is a fixed expenditure, and if we had got several millions of gallons of water a day which run to waste, which is the fact, of course we should have so much in aid of our expenditure if we could find additional customers; so that instead of its being a disadvantage, it appears to me that it would be a very great advantage, and a great encouragement to lay out a large sum of money to obtain an ample supply.

7400. (*Chairman.*) Will you put on our minutes a reference to the several Acts under which you are acting, and a description of the Acts?—The first Act obtained was the 10 & 11 Vict., cap. 203, "The Manchester Corporation Water Acts, 1847," by which the purchase of the works of the old company and the carrying out of the Longdendale scheme was authorized. The following Acts have been since obtained, by which additional powers of various kinds relating to the waterworks have been obtained by the corporation, viz.: 14 & 15 Vict. c. 79, The Manchester Corporation Waterworks Act, 1851; 17 Vict. c. 38, The Manchester Corporation Waterworks Act, 1854; 21 & 22 Vict. c. 87, The Manchester Corporation Waterworks Act, 1858; 23 Vict. c. 93, The Manchester Corporation Waterworks Act, 1860; 26 & 27 Vict. c. 68, The Manchester Corporation Waterworks Act, 1863; 28 & 29 Vict. c. 145, The Manchester Corporation Waterworks Act, 1865; 30 Vict. c. 37, The Manchester Corporation Waterworks Act, 1867.

7401. Have you any other statement which you think would be useful to this Commission?—Yes, I have a statement, which I will put in, of the charges for houses at 10*l.* and under in Manchester and several other places. It states the gross annual value, the full nett annual value, and the Manchester external and internal supply in two columns, and the charge in Glasgow, Liverpool, Dublin, Bristol, and Birmingham. I will just take one or two instances—3*l.* 10*s.* gross annual value at Manchester is 3*l.* nett annual value; for that our charge is 4*s.* externally by a stand-pipe, and 5*s.* internally, as I have explained, and it is the same up to 10*l.* We have power by the Act of Parliament to make a minimum charge of 4*s.* where externally supplied, and 5*s.* if internally supplied. In fact, we have a right to claim from the owner as the minimum charge 4*s.* or 5*s.* per annum, as the case may be, no matter what the rent of the premises may be, for a supply of water. In Glasgow the charge is 3*s.* per annum; in Liverpool, 1*s.* 8*d.*; in Dublin, 3*s.*; in Bristol, 5*s.*; and in Birmingham, 6*s.*

7402. Are all those towns supplied by the municipality or by private companies?—Glasgow is supplied by the municipality, Liverpool is supplied by the municipality, and Dublin is supplied by the municipality, and Bristol and Birmingham are supplied by companies. At Bristol the least charge is 5*s.*; and at Birmingham 6*s.* This table, which I will hand in, shows the rate from 3*l.* 10*s.* to 12*l.* Above 8*l.* gross annual value, or 6*l.* 10*s.* net, our charge would be 4*s.* 10*d.* externally, and 5*s.* internally; in Glasgow it is 6*s.* 6*d.* externally; in Liverpool, 3*s.* 8*d.*; in Dublin, 6*s.* 6*d.*; in Bristol, 8*s.*; and in Birmingham, 10*s.* 4*d.* They very soon leave us behind when we get to a little higher rentals. Then, going to 12*l.* gross, or 10*l.* net value, the Manchester charge is 7*s.* 6*d.*, either externally or internally; Glasgow, 10*s.*; Liver-

J. Heron, Esq.
2 April 1868.

pool, 5*s.* 8*d.*; Dublin, 10*s.*; Bristol, 12*s.*; and Birmingham, 16*s.* 9*d.*

7403. (*Sir B. Phillips.*) In all those cases where they are supplied by companies it would appear that the water is much more expensive than where they are supplied by corporations?—Yes; in Birmingham it is 16*s.* 9*d.*, that is a company; and in Bristol it is 12*s.*, and that is a company. There is no public rate in Bristol, and there is no public rate in Birmingham, so that that may be one reason why their charge for domestic supply is greater.

The witness delivered in the following table:—

Comparison of Charges for supply to Cottages in various Towns.

The witness withdrew.

Adjourned *sine die.*

Wednesday 9th December 1868.

PRESENT:

Sir JOHN THWAITES in the Chair.

Alderman Sir Benjamin Phillips.
Colonel Harness, C.B.
Thomas Elliott Harrison, Esq.
Joseph Prestwich, Esq.

J. F. Bateman, Esq.
9 Dec. 1868.

John Frederic Bateman, Esq., further examined.

7404. (*Chairman.*) We understand that you are desirous of stating shortly to the Commission the result of your experience of the rainfall during the year 1868, and correcting so far as that rainfall may render it necessary, the previous figures which you have put in. I am desired to state to you that the Commission are very anxious not to go into any other question than that single one which I have indicated?—The season extending over 1864 and 1865 was a severer period in many parts of the country than the drought of 1868, and the Commission will hardly have the fullest information unless I give the rainfall of that period also. With respect to 1868 I have obtained the most accurate information as to the result of the drought, showing the quantity of rain which was received during its continuance, and the quantity of water which was delivered at Manchester, Dublin, Liverpool, and at the Loch Katrine and Gorbals Waterworks of Glasgow, at Blackburn, and at Halifax. I can also give the returns of the actual gaugings of streams which bear very directly upon the whole question. I will give it you very shortly, and I have endeavoured to express the general results in tables.

With regard to the Manchester Waterworks, we will begin first with the drought of 1868. The drought commenced on the 27th of April and terminated on the 24th of September, a period of about 150 days. I will not trouble the Commission with all the figures which you will have before you, but there was a certain quantity of water in store on the 27th of April, and a small quantity was pumped by the Gorton pumping engine, making together a total of 2,767,000,000 gallons which the Corporation had in store and pumped by the engine for the supply of Manchester. At the end of the drought on the 24th of September there remained in store in round numbers 435,000,000 gallons, showing that out of store they had taken 2,331,000,000. The quantity supplied during the drought to the mills was in round numbers 1,623,000,000 gallons, and to the city 1,839,600,000 gallons, making together 3,462,600,000 gallons in round numbers, showing that beyond the quantity which they had taken out of store, they had derived from other sources 1,131,000,000 gallons of water. That was yielded by the rain and springs during that period, and the quantity amounted to a depth of 2·77 inches of rain flowing from the 18,000 acres of drainage ground which constitutes the collecting ground of the Manchester Waterworks, or to an average flow during the whole of that period of ·776 of a cubic foot per second from every 1,000 acres. The following table will show how these results are arrived at:—

MANCHESTER CORPORATION WATERWORKS.—DROUGHT of 1868.

The drought commenced on the 27th April and terminated on the 24th September, a period of about 150 days.

	Gallons.
Quantity of water in store April 27th	2,740,000,000
Pumped by the Gorton engine between August 12th and October 8th	27,000,000
	2,767,000,000
Quantity of water in store, 25th September	435,679,203
	2,331,320,787

Quantity supplied during the drought.

			Gallons.
To mills full supply to 10th August, 105 days, at 12,728,568 per day			1,336,499,640
From 10th August to 24th September, 45 days, at 6,364,284 per day			286,392,780
Total to mills			1,622,892,420
To City.			
Unlimited constant supply to 3d August, 98 days, at 14,330,450	1,404,484,145		
From 3d August to 24th September, the above water was shut off at night from 6 p.m. to 6 a.m., 52 days at 8,368,008	435,136,407	1,839,620,552	3,462,512,972
Balance being the quantity supplied by springs and rain			1,131,192,185

The yield of rain and springs is equal to 2·77 ins. of rain flowing off the 18,000 acres of drainage ground, or to a flow of ·776 cubic feet per second from every 1,000 acres. The rain during this period was 9 ins.; the loss therefore, 6·23 inches.

The diagram which I have placed before the Commission shows what the water in store in the Manchester Waterworks, during all those years from 1864 to 1868 was, the red horizontal line representing the ordinary level of the storage, and the other lines representing the manner in which the reservoirs went down during those years. We increased our storage in March 1868 but the drought this year brought the quantity down to 435,000,000 gallons, which was the lowest point on the 24th of September. The ·776 which I have mentioned is the mean result of the 150 days, but in order to show how the streams went down, and what their produce was during that period in which it may be said that no rain fell, which was from May to August—I have worked it out in four different periods:—

MANCHESTER CORPORATION WATERWORKS.—DROUGHT of 1868.

Memorandum as to yield of streams during periods of minimum rainfall.

1st.—From June 1st to 29th 1868=28 days. Rainfall at Rhodes Wood 0·58 ins.—at Woodhead 0·42 ins.

			Gallons.
Quantity in store June 1st 1868	both exclusive of		2,287,000,000
Do. „ 29th „	Prestwich Reservoir		1,693,000,000
Quantity supplied out of store			594,000,000
Quantity supplied:			
To City—14,440,180 gallons per day on the average for 28 days		404,325,037	
To Mills—14,850,000 gallons per working day for 24 days		356,400,000	
Total quantity supplied		760,725,037	
Deficiency supplied by district			166,725,037
			760,725,037

166,725,037 gallons, or 26,676,006 cubic feet, equal ·612 cubic feet per second from every 1,000 acres.

2d.—From June 29th to August 3d 1868 = 35 days. Rainfall at Rhodes Wood 0·68 ins.—at Woodhead 0·66 ins.

		Gallons.
Quantity in store, June 29th 1868, including estimated quantity in Prestwich Reservoir		1,713,000,000
Do. August 3d „	do.	893,000,000
Quantity supplied out of store		820,000,000
Quantity supplied:		
To City—14,884,606 gallons per day on the average for 35 days	520,961,208

Balance produce of the district for 63 days - - - - - - - -	313,186,245
	1,727,186,245

313,186,245 gallons, or 50,109,799 cubic feet = ·5114 cubic feet per second from every 1,000 acres.

SUMMARY.

	Cubic feet per second from every 1,000 acres.
District produced between June 1st and 29th, 1868, 28 days (with ·58 ins. of rain at Rhodes Wood and ·42 ins. of rain at Woodhead) - - -	0.612
„ June 29th and August 3d, 1868, 35 days (rainfall at Rhodes Wood, 0·68 ins.; rainfall at Woodhead, 0·66 ins.) - - -	·43
„ July 27th and August 3d, 1868, = 7 days - - - -	0·329
„ June 1st and August 3d, 1868, = 63 days - - - -	0·5114

First of all, from the 1st of June to the 29th of June, 28 days, the rainfall was about half an inch; and the produce of the district was equal to ·612 of a cubic foot, or just two-thirds of a cubic foot per second from every 1,000 acres. Then from the 29th of June to August 3d, the rainfall being exactly two-thirds of an inch in that time, the produce of the district was ·43 of a cubic foot per second from every 1,000 acres. That was the average of that period. At the end of July and the beginning of August the streams had got down to their lowest. From the 27th of July to August 3d, seven days, there being only one-tenth of an inch of rain, the produce of the district was ·329 of a cubic foot per second from every 1,000 acres. From June 1st to August 3d, which includes the whole period during which I have given the separate details in three different portions, the average produce of the district was ·5114 of a cubic foot per second from every 1,000 acres. It will be in the recollection of the Commission that I stated in my previous evidence that the average yield of this district was as nearly as possible half a cubic foot per second from every 1,000 acres during the continuance of a drought. That was true for a period of about 70 days, but the average of the 150 days, which included the time during which the streams were somewhat swollen after the termination of the wet weather in March and April, was nearly eight-tenths, or, speaking more accurately ·776 of a cubic foot per second per 1,000 acres. So that while I was quite correct as to the quantity of water yielded during the extremity of the drought during which it may be said that no rain fell, I under-estimated the ordinary produce of the district during the 150 days of what for waterworks purposes would be considered drought, but would not be considered drought for agricultural purposes. At the end of the above Table you will find stated shortly the figures I have given —in the first division ·612, in the second ·43, in the third ·329, and the average of the whole period ·5114. These results are given from the quantity of water actually collected in the reservoirs, (which during that time did not run over,) the capacity of which we know at every inch in depth, and from the quantity of water actually delivered as measured through gauges. During a portion of that period, for another purpose entirely, I had the streams flowing from rather more than 3,000 acres in the upper portion of the drainage district of the Manchester Waterworks carefully measured. That was at the commencement of August, and on referring to the table I have given you will see that the gross produce of the whole district was ·329 of a cubic foot per second. From the 3,000 acres which formed a portion of that, and which was by no means the most productive portion as regards spring water, it averaged ·28, being a little less than the average of the whole 18,000 acres from which the water is obtained. I merely mention that to show how nearly one corroborates another.

7405. Did you gauge at the point of discharge into the reservoir?—The first measurements which I gave, are measured as it were by a great basin, because the reservoirs are in fact great bowls into which the water is received from the whole 18,000 acres, and we know their capacity at every inch in depth.

7406. How did you measure the net result of the rainfall on the 3,000 acres?—Over a gauge put down across the stream, through a notch.

7407. And did one stream take the whole?—No, there are two streams—one bringing the water from 1,751 acres, and the other from 1,436 acres, making together 3,187 acres.

7408. Did you make a section of the stream?—We put a gauge across it, and measured the depth flowing over it, and ascertained the volume by well-known formulæ. I can also show the Commission by diagrams (See Appendix B. H.), which are very valuable indeed, the results of gauging which were taken during the same period at the Halifax Waterworks. One diagram shows the quantity of water flowing from two streams in the Halifax Waterworks, one of which has a drainage area of 2,325 acres, and the other of 1,999 acres. During January, February, and March, it was very wet, April was dry till towards the end of it—and from that time to the beginning of August with very little exception it is a continual decrease in quantity. At the commencement of August there is an almost uniform slight increase, and if you look at both the streams you will observe that they exactly correspond and tell the same story. I want to show how closely correspondent all those districts are with reference to the yield of water. In May, from the period at which the flood may be said to have run off, the average volume of the stream, swollen occasionally by slight showers, was ·554 of a cubic foot per second per 1,000 acres; in June, very little rain indeed having fallen, it was ·28 of a cubic foot per second per 1,000 acres; in July, still without rain, it was ·225 of a cubic foot per second per 1,000 acres; in August, a little rain having fallen during the period to which those observations apply, it was ·272 of a cubic foot per second per 1,000 acres; and the average of the whole period, from about the 4th of May to the 21st of August, or a little beyond the middle of August, was ·332 or one-third of a cubic foot per second from each 1,000 acres during that most extraordinary drought of 1868. Then if you go to the River Hebden, which has a drainage area of upwards of 9,000 acres, and therefore taking a larger portion of spring water, you find that in May the average quantity from those 9,000 acres was ·756 of a cubic

oot per second per 1,000 acres; in June, ·418; n July, ·305, and in August ·324, the average of the whole period being ·452, coming very closely upon he half cubic foot per second which I stated was the general result; and if you take that with what is the case at Manchester, which is ·5114, you almost exactly get half a cubic foot per second as the mean between the two series of observations.

I would wish to take Liverpool separately, because it is very important information which Liverpool gives, and it would be convenient to keep it all together, embracing as it does a period of five years from 1861 to 1865 inclusive, which included 1864 and 1865, very severe years, and then 1864, 1865, and 1866, together with the long drought of 1868; therefore, instead of Liverpool, I will now take the case of Dublin in 1868, and hand in the following table:—

DUBLIN WATERWORKS.—DROUGHT of 1868.

Drainage ground - - -	acres	14,080
Capacity of reservoir, Vartry Lough -	c. ft.	380,000,000
Or	gallons	2,374,358,300

Equal to 25,568 cubic feet of storage to each acre of ground.

Drought commenced May 1st, ended Sept. 18th=141 days.

	Gallons.
Quantity of water in store at commencement	1,590,176,513
Ditto end of drought - - -	877,731,138
Total drawn from stores - -	712,445,375
Quantity discharged from reservoir during this period - - - -	2,109,728,160
Supplied by streams and rain - -	1,397,282,785

Equal to 1·303 cubic feet per second from every 1,000 acres, and to 4·37 ins. of rain flowing off ground out of 11·298 ins. which fell.

The drainage ground to the Dublin Waterworks is 14,080 acres; the capacity of the Roundwood reservoir or Vartry Lough is 380,000,000 cubic feet. At the commencement of the drought, which was on the 1st of May, the Vartry reservoir, which had only been recently repaired, was not full, but it contained 1,590,000,000 gallons of water; at the end of the drought it contained about 878,000,000 gallons. There were therefore drawn from store 712,000,000 gallons; and the quantity discharged from the reservoir during this period for the supply of Dublin was 2,109,000,000 gallons, showing that they had obtained from other sources 1,397,000,000 gallons. That of course was obtained by the produce of the streams and rain, the whole quantity being equal to 1·303 cubic feet per second from every 1,000 acres, and to 4·37 inches of rain flowing off the ground out of 11·298 inches which fell in that period. The drought continued during 141 days, and you will see that the produce of the streams during those 141 days was one and one-third cubic foot per second, very nearly, as against ·776 of a cubic foot per second, which the Manchester water works district yielded during the same period within nine days.

7409. There is therefore a much larger net result in this case than in the case of Manchester?—Yes, a much larger net result. The next case that I will give is that of Glasgow for 1868, and first of all of the Loch Katrine district—with regard to which I will hand in the following table:—

GLASGOW CORPORATION WATERWORKS.—DROUGHT in the LOCH KATRINE DISTRICT, 1868.

Drought may be said to have commenced on the 30th May and ended on the 8th August, or 70 days.

		Gallons.
Water in store in Lochs on 30th May 1868 - - - - - - - -		8,640,109,163
Quantity of water discharged from Loch Katrine to service reservoir, from 30th May to August 8th, 1868, = 24,174,990 gallons daily - - - - - - -	1,692,249,308	
Quantity of water discharged from Loch Venechar during same period as compensation, =48,712,206 gallons daily - - - - - - - -	3,409,854,432	
Total supplied - - - - - - -	5,102,103,740	
Quantity in store on 8th August - - - - - - - - -		4,991,217,229
Quantity supplied out of store - - - - - - - - -		3,648,891,234
Quantity produced by stream and rain during the period of 70 days - - - - -		1,453,212,506
Total supply - - - - - - - - - -		5,102,103,740

The quantity supplied by rain and springs during the drought was equal to 0·839 cubic feet per second from every 1,000 acres of drainage, and to 1·39 ins. of rain from 45,800 acres out of 4·65 ins. average rainfall during this period.

Storage provided (8,640,000,000 gallons, or 1,382,400,000 cubic feet) equal to 30,183 cubic feet for every acre of drainage ground.

Scheme intended to supply to city - - - - -	50,000,000	gallons per day.
And compensation to streams - - - - - - -	40,500,000	„ „
Total supply - - - - - - - -	90,500,000	„ „

Storage and streams (8,640,109,163 storage + 1,453,212,506 streams and rain = 10,093,321,669 gallons), would supply 90,500,000 gallons daily for 70 days, and leave in store at the end of that time 3,758,321,669 gallons, equal to the supply of the same quantity for 41½ days more, even supposing the streams to yield nothing during these 41½ days, and they would probably have yielded 20,000,000 gallons per day, so that the storage would have lasted for upwards of 50 days, making up the 120 days provision on which the scheme was laid out.

The drought there was not a long one; it hardly may be considered a drought at all, for it lasted only about 70 days, beginning on the 30th of May and ending on the 8th of August. The gross result of that was that the quantity supplied by rain and springs during those 70 days (which you will observe included that extreme period of June and July up to the 8th of August, which produced that very small quantity of rain in Halifax and Manchester, as I have already shown you), was ·839 cubic feet per second from every 1,000 acres, being equal to 1·39 inches of rain from 45,800 acres of drainage ground out of 4·65 inches which actually fell during the period.

7410. That is less than the other result?—Yes, but it is only for 70 days.

7411. Is not the ratio less?—No, it is rather more; it is about one-third. The produce of the district during those 70 days was equal, if it had been all the result of rain, to 1·39 inches out of 4·65 inches which actually fell.

7412. That is less than the proportion in the case of Dublin?—Yes, but the drought at Dublin extends over 141 days. We only drew from Loch Katrine and Loch Venechar for the supply of the mills and the city together, about 73,000,000 gallons of water per day, being 48,750,000 gallons as compensation to the river, and rather more than 24,000,000 gallons to the city of Glasgow. We are entitled to take for Glasgow 50,000,000 gallons a day. I therefore worked out what would be the quantity of water which we should be able to supply, and for how many days, supposing we were drawing the full

J. F. Bateman, Esq.

9 Dec. 1868.

50,000,000 gallons and giving the full amount of compensation, and I find that we should have been able to have supplied the full quantity of compensation, and the full amount of 50,000,000 gallons per day for 120 days, which is exactly the period upon which the Loch Katrine Waterworks were originally designed before our experience of the drought of 1864 and of 1865, or of 1868—so that the Loch Katrine Waterworks proved to be equal to the supply to the very day to which I calculated them in 1853 or 1854, when I laid them out, and the calculation seems to be correct, even in a drought like that of 1868.

The Gorbals Waterworks is the next case, as to which I will hand in the following table :—

GLASGOW CORPORATION WATERWORKS, GORBALS DISTRICT.—DROUGHT of 1868.

Drainage area - - -	acres	2,560
Capacity of reservoirs - -	cubic feet	134,239,786
Or - -	gallons	838,998,662

Storage equal to 52,437 cubic feet per acre.

Average rainfall per annum - - -	inches	49
Average loss - - - - -	,,	10¼
Available rain - - -	,,	38¾

Drought of 1868 extended over 189 days, commencing March 29th, and terminating October 3d.

	Gallons.
Quantity of water in store at commencement	838,998,662
In store at end of drought - - -	220,591,199
Taken from store - - -	618,407,463
Quantity of water delivered during the period to city and to river for compensation, average 5,256,581 for 189 days - -	993,493,836
Supplied by rain and streams -	375,086,373

The quantity supplied by rain and springs during the 189 days was equal to 1·43 cubic foot per second from every 1,000 acres; and to 6·45 ins. of rain over the whole drainage ground, out of 18·19, the actual rainfall.

The quantity of water actually delivered was at the rate of nearly 33 ins. of rain collected per annum. The water left in store was equal to about 7 in. more, together, 40 in.

This is a very useful instance, for the drought in 1868 there lasted over 189 days. The drainage area is 2,560 acres; the capacity of the reservoirs is 134,000,000 cubic feet, equal to a storage of 52,437 cubic feet per acre. A great deal depends upon the amount of storage in proportion to the contributing area as to the means which we have of giving a large supply. The result in this case is that after making allowance for that which was taken out of store, and putting against that the quantity which was actually delivered, we find that there were supplied by rivers and streams 375,000,000 gallons during the period of 189 days as against 618,000,000, which was taken out of store. The quantity supplied by rain and springs during this period was equal to 1·43 cubic feet per second per 1,000 acres, or nearly a foot and a half—and to 6·45 inches of rain over the whole drainage ground, out of 18·19 inches, which was the actual amount of rainfall during the period. The quantity of water actually delivered was at the rate of nearly 33 inches of rain collected per annum, and the water left in store was equal to about 7 inches more—so that with that amount of rainfall, and with a storage equal to about 52,000 cubic feet per acre, they were capable of delivering through a drought like that of 1868 at the rate of 40 inches of rain per annum actually collected.

The next case that I will take is that of Blackburn. This, although a very small acreage, and a small supply, is a case deserving of considerable attention, and I will hand in the following table :—

BLACKBURN WATERWORKS.—DROUGHT of 1868.

Population supplied about - -	persons	60,000
Average daily supply - -	gallons	1,150,000
Drainage ground for town purposes	acres	880
Gross capacity of reservoirs for ditto	gallons	410,000,000
Or	cubic feet	65,600,000

Being equal to 74,545 cubic feet per acre of drainage ground.

The drought commenced on the 27th March. The reservoirs were not then full.

	Gallons.
The quantity of water in store was approximately - - - - - -	300,000,000
The drought ended about the middle of September, say the 25th, the same as in Macchester. The quantity then in store was about - - - - - -	104,000,000
Taken out of store - -	196,000,000
Supply to town for 182 days at 1,150,000 gallons per day - - - -	209,000,000
Supplied by rain and springs - -	13,300,000

The quantity supplied by rain and springs during the 182 days of drought was only equal to ¾ of an inch in depth over the drainage ground out of 12·8 ins. of rainfall, but these calculations, though very near the truth, are only approximate.

The present supply to Blackburn is equal to but 19 inches of available rain. The reservoirs once full are equal to 20½ ins. depth of rain over the whole drainage ground, and would, therefore, give out a quantity equal to that depth for a whole year, without any aid from rain, or to 41 in. for a period of 186 days.

The rainfall on the average of 10 years is 44 ins., and the reservoirs are capable of utilizing more than the average available rain. They have been made in anticipation of receiving supplies from additional ground which has not yet been appropriated.

Formerly they had only a small amount of storage in proportion to the ground which they had to collect from, and in a season like that of 1868, they would have been short of water, although they were supplying but a portion only of that which actually flowed from the ground; but in course of last year we completed a very large reservoir which was intended to hold the water of a large district, which, however, has never been brought to it. Now the reservoirs collect every drop of water which falls, and would collect more than what falls, and that will last them for some time longer. The drainage area contributing to the supply of the town is only 880 acres, but the gross capacity of the reservoirs as they now exist is 410,000,000 gallons, being equal to 74,545 cubic feet of water storage for every acre of collecting ground. The population is about 60,000, and the average daily supply is 1,150,000 gallons. I cannot give you those calculations with absolute correctness, because of the older reservoirs we have not the capacity at every inch in depth, of the new one we have, but those calculations are very near the truth.

7413. Can you give us the net result?—Yes. The quantity of water in store on the 27th of March, when the drought commenced, was 300,000,000 gallons; at the end of the drought on the 25th of September, there remained 104,000,000 gallons in store; there were therefore taken out of store 196,000,000 gallons; and the supply to the town during that period, which was 182 days, was 209,000,000 gallons, leaving the quantity supplied by rain and springs 13,300,000 gallons, that is equivalent to only three-fourths of an inch in depth over the drainage ground, out of 12·8 inches of rainfall; but as I said before, those calculations are only approximate. It is a bare hill side of nearly 900 acres, with scarcely a spring upon it; but the important result is that where you have a very large amount of reservoir room, you may in fact store not only all the rain which falls in average years, but that which falls in excessively wet years; and with such reservoirs as they have at Blackburn, not one single drop of water which flows off the ground need be run to waste. If they were only to deliver water equivalent to the average supply, there would not be one single drop of water run to waste, and they would be able to give the full average of the whole available quantity flowing from the district.

7414. How do you explain this, that in a very hilly district of 900 acres you have the result of but three-fourths of an inch available for the water supply out of 12·8 inches?—I am not quite sure as to the calculations being correct within three-fourths of an inch. It was excessively dry there during that period—it is a pastoral district which is covered with vegetation and wholly grassland—and during that period a large portion of the rainfall would no doubt be absorbed by vegetation.

7415. If it is a hilly district, the water would find its way more rapidly into the channel, would it not?—That is governed by the nature of the vegetation, but I believe the three-fourths of an inch to be less than the truth. I have no doubt that if those calculations were accurately taken, the three-fourths of an inch would have to be doubled, or perhaps more.

7416. Will you now take the case of Liverpool?—Yes. I propose to give you Liverpool, first, for the whole series of five years commencing with 1861 and ending with 1865, then for the drought, which in Liverpool extended from March 1864 to June 1866, (and that was the most trying period that I find they have ever passed through, or any waterworks have passed through within any record), and then for the drought of 1868:—

LIVERPOOL CORPORATION WATERWORKS, RIVINGTON.—1861 to 1865 inclusive.

Drainage area - - - -	acres	10,000
Average rain for 17 years - - -	inches	46
Mean rains of 1861 to 1865 inclusive=five years	„	44
Mean of 64 and 65 being only - - -	„	37

Storage 2,940,000,000 gallons, or 470,000,000 cubic feet, = 47,000 cubic feet per acre.

Average yield per day during above period:—

	Gallons.
To mills for compensation - - -	8,300,000
To town and work - - -	12,472,672
	20,772,672

Equal to 3,323,630 cubic feet × 365 day = 1,212,064,950 cubic feet.

10,000 acres = 435,600,000 square feet, = 2·782 or 33½ in. gross produce of district out of 44 in., showing a loss of 10½ ins.

Quantity actually collected and delivered:—

	Gallons.
To River as compensation - -	8,300,000
To town - - - - -	10,544,112
	18,844,112

Being equal to 30 ins. or 10 per cent. less than the average yield.

The drainage area of the Liverpool Waterworks is 10,000 acres, the average rainfall for 17 years is 46 inches, the mean rain of the five years under consideration, 1861 to 1865 inclusive, was 44 inches, the mean of 1864 and 1865, being the two dryest years which occurred during that period, was only 37 inches; the storage was then equal to about 47,000 cubic feet per acre. The average yield per day during the above period, taking mills, and town, and waste together, that is to say, the gross quantity which flowed off the ground, was 20,770,000 gallons per day, equal to a gross produce in the year of 33½ inches per annum out of 44 inches, which fell during that period, showing a loss by evaporation, absorption, and so on of 10½ inches. The quantity actually collected and delivered was 18,844,000 gallons per day, being equal to 30 inches of water actually delivered, or 10 per cent. less than the average yield. Then the next information with reference to Liverpool that I have to give to the Commission, is with regard to the drought of 1864, 1865, and 1866, of which the following table is a summary:—

LIVERPOOL CORPORATION WATERWORKS.—DROUGHT of 1864, 1864, and 1866,

	Gallons.
Reservoirs full on 11th March 1864 -	2,940,000,000
On 28th October 1865, being then at their lowest point - - - -	228,000,000
Decrease - - -	2,712,000,000

During the same period there was taken to Liverpool and given to rivers, 596 days — Gallons. 11,240,000,000

Obtained from springs and rain - 8,528,000,000

$$\frac{11{,}240{,}000{,}000}{596} = 18{,}860{,}000 \text{ gallons per day.}$$

Or To mills 8,300,000

To town 10,560,000

The reservoirs being then nearly exhausted, and a winter of only moderate rainfall following, this supply could not have been maintained, for the average yield of the first five months of 1866 was only (8,736,000 + 8,300,000) 17,036,000 gallons per day. Supposing this to represent the yield of November and December, the works would have given the full compensation to the mills, and rather more than 9,000,000 gallons per day to the town, say with safety 17,300,000 = 28 inches per annum.

The reservoirs were full or very nearly full on the 11th of March 1864, and they then contained 2,940,000,000 gallons; they reached their lowest point on the 28th of October 1865, having then fallen to 228,000,000, therefore the store had decreased 2,712,000,000 gallons. During the same period, that is for 596 days, there were taken to Liverpool and given to the river 11,240,000,000 gallons, showing that there was obtained from springs and rain 8,528,000,000. The reservoirs being then nearly exhausted, that is to say, in October 1865, and a winter of only a moderate rainfall following, the supply could not have been maintained at what they had been giving, which was an average of 18,800,000 gallons per day, that being composed of 8,300,000 gallons as compensation to the mills, and 10,560,000 to the town. They could, with safety, have given, up to the 1st of June 1866, when the drought ceased, 9,000,000 gallons per day to Liverpool, or rather more, and the full amount of compensation, that is, 8,300,000 gallons, making a total of 17,300,000 during that extreme period. Therefore, as they were delivering and had delivered 10,560,000 gallons previous to their extremity in October 1865, they had been exceeding their means of supply by about 1,500,000 gallons per day, and they ran short at the end of 1865. They were obliged to diminish their supply in consequence of having been delivering up to that period more than the quantity which their district enabled them to give. With the storage that they then had, they could have delivered throughout that period 1864 and 1865, and up to Midsummer 1866, a quantity equal to 28 inches of rainfall per annum. They got an Act of Parliament in 1866, by which they were enabled to make additional storage, and that would enable them to collect the waste water of wet periods and to add about 1,250,000 gallons per day to the 9,000,000, so that when that reservoir is completed, and they are now constructing it, they will be in a condition to deliver through such a period as 1864 and 1865, about 10,250,000 gallons per day to the town of Liverpool, besides giving full compensation to the mills at the amount at which such compensation stood up to 1866.

The following table gives the state of things for the year 1868:—

LIVERPOOL CORPORATION WATERWORKS, RIVINGTON DISTRICT.—DROUGHT of 1868.

Drainage area - -	acres	10,000
Capacity of reservoirs - -	cubic feet	485,000,000
Or - -	gallons	3,025,000,000

Storage equal to 48,500 cubic feet per acre.

Drought of 1868 extended over 161 days, commencing April 28th and terminating October 6th.

Quantity of water in store at commencement	3,025,000,000
In store at end of drought - - -	722,000,000
Taken from store - - -	2,303,000,000

Quantity of water supplied during this period
to city - 9,987,570 gallons per day
And for compensation to river - 6,465,840

Total daily aver. 16,453,410 for 161 days = 2,649,000,000

Supplied by rain and springs - - 346,000,000

J. F. Bateman, Esq.

9 Dec. 1868.

The quantity supplied by rain and springs during the 161 days of drought was equal to ·398 cubic feet per second, for every 1,000 acres of drainage, and to 1·525 inches of rain flowing off the whole drainage ground out of 12·20 inches which fell during this period.

If the whole of the water in store at the commencement had been exhausted at the end of 161 days of drought, it would have represented a total daily supply from the district equal to:—

	20,937,880 gallons per day.
Deducting for compensation a portion having been purchased	6,465,840
Left for town	14,472,040

In 1868 the drought extended over 161 days, commencing on the 28th of April, and terminating on the 6th of October; it lasted longer in Liverpool than it did in some of the surrounding districts. The quantity yielded by rain and by springs during that period was equivalent to ·398 of a cubic foot per second for every 1,000 acres, or to 1·525 inches of rain out of 12·20 inches which fell. The district yielded a very small amount of actual contribution to the reservoirs during that period of drought; they only got 1½ inches out of about 12 inches which fell, showing that they lost 10½ inches, but a large portion of the Liverpool drainage ground is flat land; it nowhere rises to more than 1,200 or 1,300 feet, and the mean elevation of the whole district is only between 700 to 800 feet, and there is a great deal of peat upon the tops of the hills, and a great deal of flat cultivated land on the westerly slopes of the reservoirs.

7417. Then if the general water line were depressed, especially on peaty soil, the absorbing power would be enormous?—Yes. It is a strong contrast to the state of Manchester and the state of Dublin. They could have delivered during the drought of 18 rather more than 12,000,000 gallons to the town of Liverpool, had the compensation to the mills remained the same; but they bought up a certain portion of the compensation in 1866, and therefore they could deliver more; but had the compensation to the mills remained the same, they could have delivered rather more than 12,000,000 gallons of water per day to Liverpool against only a little more than 9,000,000 in 1864 and 1865.

I will now refer to the drought of 1864 and 1865 in Manchester, and will hand in the following table:

MANCHESTER CORPORATION WATERWORKS, DROUGHT OF 1864.

	Acres.
Drainage area	18,000
Drought commenced May 24 and ended October 11th, lasting 140 days.	Gallons.
Quantity of water in store at commencement	1,779,000,000
Do. at end of drought	1,253,000,000
Quantity taken from store	526,000,000
Quantity supplied during this period:	
	Galls. pr. day.
To mills for compensation	12,728,568
To town supply on average	11,070,000
Total daily	23,798,568
	× 140 days = 3,331,799,520
Supplied by rain and springs	2,805,799,520

The quantity supplied by rain and springs during this period is equal to 2·05 cubic feet per second from every 1,000 acres of drainage, and to 6·85 inches of rain flowing off the ground out of 15 inches actual rainfall during this period.

The drainage area is 18,000 acres; it is a little more than that, but there is an allowance to be made for some water which is abstracted by the mill owners. In 1864 the drought commenced on the 24th of May, and ended on the 11th of October, lasting 140 days. Without going over all the figures, the important object of them is to show that the quantity supplied by rain and springs during this period of drought is equal to 2·05 cubic feet per second from every 1,000 acres and to 6·85 inches of rain flowing off the ground out of 15 inches, which was the actual rainfall. The following table shows the state of things for 1865:—

MANCHESTER CORPORATION WATERWORKS, DROUGHT OF 1865.

Drainage area	18,000 acres.
Drought commenced April 18th and extended to October 8th, lasting 172 days.	Gallons.
Quantity of water in store at commencement	2,384,000,000
Ditto at end of drought	912,000,000
Quantity taken from store	1,472,000,000
Quantity of water supplied during this period	
To mills for compensation	12,728,568
To town supply	11,833,000 total.
	24,561,568 total daily.
	average × 172 days = 4,224,589,696
Supplied by rain and springs	2,752,589,696

The quantity supplied by rain and springs is equal to 1·6467 cubic feet per second for every 1,000 acres of drainage and to 6·74 inches of rain flowing off the ground out of 14½ inches actual rainfall during the period.

In 1865 the drainage area remaining the same, the drought commenced on the 18th of April, and extended to the 8th of October, lasting 172 days. After showing what we had in store at the commencement, and at the end of the drought, and what was supplied, it results that the quantity supplied by rain and springs was equal to 1·6467 of a cubic foot per second for every 1,000 acres, and to 6·74 inches of rain flowing off the ground out of 14½ inches, which actually fell during that period.

7418. You get a much greater result here?—Yes, in 1864 and 1865, although it was more severe in Liverpool; perhaps if we had been supplying quite the same quantity of water, it would have been nearly as severe in 1868.

7414. In 1864 it was 6·85 out of 15 inches?—Yes. You will see at once the state of things if you look at this diagram (*producing a diagram*). I have endeavoured to tabulate in a short form the information which I have been giving the Commission, and I want to draw their attention specially to the different amount of storage in the various districts as to which I have been giving the information, and I will hand in the following table:—

TABLE 12.—Showing the YIELD and QUANTITY of WATER supplied during the Drought of 1868 at the various Waterworks named.

Name of Place.	Drainage Ground. — Acres.	Storage available.		Drought.			Rainfall during Period of Drought, — Inches.	Flow off Drainage Ground.			Quantity actually supplied.			Equal to available Rainfall per Annum of Inches.	Total Quantity which might have been supplied had available Storage been exhausted. — Gallons per Day.	Equal to Gallons per Day from every 1,000 Acres of Drainage Ground.	Equal to available Rainfall per Annum of Inches.
		In Million Cubic Feet.	Cubic Feet per Acre of Drainage Ground.	Commenced.	Ended.	Lasted. — Days.		Equal to Rainfall of Inches.	Equal to Cubic Feet per Second per 1,000 Acres.	Equal to Gallons per Day per 1,000 Acres.	From Store. — Gallons per day.	From Springs and Rain. — Gallons per Day.	Total. — Gallons per day.

J. F. Bateman, Esq.

9 Dec. 1868.

In our Manchester Waterworks we are at present incomplete. We are behindhand in several of our reservoirs which we are now constructing, and we are beforehand with the quantity of water which we are supplying, so that we are not quite equal to what we should be in storage, and therefore we were not able to give the full supply of water which we could have desired during the last drought. Our available storage in Manchester is equal at present to only 24,000 cubic feet of water per acre of collecting ground. In Liverpool the storage is equal to 48,500; in Dublin it is equal to 25,500; at Loch Katrine it is equal to 30,000; and, at Gorbals it is equal to 52,000. The storage for Wales according to the plans which I have laid before the Commission, omitting the service reservoirs near Stanmore, is equal to 51,589 cubic feet for each acre of collecting ground. The result is that with the several amounts of storage named, the produce from each district during the drought of 1868, at all the various places where actual observations have been taken, is as follows: If you look at the heading called "Quantities actually supplied," and if you look at the column following that, you will find that in Manchester we did supply during the period of the drought for 150 days a quantity equal to 20·47 inches of annual rainfall. Liverpool did supply a quantity equal to 26½ inches. Dublin did supply at the rate of 17½ inches. Loch Katrine at the rate of 25·6, and Gorbals at the rate of 33 inches. These were the quantities actually supplied without reference to the capabilities of the district. Then if you follow on to the next columns, you will find that they had not only supplied that which was produced by the district, but they exhausted their store at the end of that drought. The quantity which they did supply during that very long drought of 1868 was equal to a depth of 20½ inches in Manchester per annum over the whole district, and if we had supplied more than 20½ inches, we should have been short during the drought.

7420. Are we to understand that this 20½ inches is 20½ inches up to January last when this table was made, or have you calculated and spread the 20½ inches over the whole 12 months?—Over the whole 12 months. The quantity which we did supply was equal to a safe supply during the drought at the rate of 20½ inches. If we had calculated upon 24 inches, we should have been 3½ inches short during the drought.

7421. When you speak of supply do you mean supply for purposes of consumption and for municipal purposes, or do you mean the quantity of water available for supply?—The first column is the actual quantity which was drawn from the reservoirs for all purposes, whether for the city, for municipal purposes, or for domestic, or for mill consumption, it was equivalent over the whole year to 21 inches.

7422. (*Sir Benjamin Phillips.*) Was it equal to your requirements?—It was nearly equal to the requirements. There were a few weeks during which we had to shut off the water during the night at Manchester. If we had exhausted all the store which we had we could have delivered at the rate of 23·6 inches. In Liverpool they could have delivered at the rate of 33·68 inches. In Dublin they could have delivered 24·6. In Loch Katrine they could have delivered at the rate of 50·64; and in Gorbals they could have delivered at the rate of 40·37 inches in the course of a year; that is, with the several amounts of storage, which vary as you will see from the table.

7423. (*Chairman*). That is to say, supposing that the storage had been equal to the fall?—No; taking their storage as it is, which in one case is only 24,000 cubic feet to an acre, and in another case is equal to 52,000 cubic feet to an acre, so that with a smaller storage, everything else being nearly the same, they were only able in the one case to deliver at the rate of 23·6 inches, and in the other at the rate of 40·37 inches; the larger amount of storage by catching the water of wet seasons enabling them to deliver a larger quantity of water. Then I have applied that to the Welsh district which I propose to supply London from; 130,000 acres is the drainage area of that district; the total provision storage is 6,709,000,000 cubic feet; that is equa 51,589 cubic feet of storage for each acre, nearly e to that which is provided at Gorbals, which is largest provision of any of the five places that I l given you above. The drought lasted for 144 da Wales. It really lasted only about 110 or 120 d but putting it on to when the drought broke u other places it makes it 144 days, as against 15 Manchester, 161 in Liverpool, 141 in Dublin, 7 Loch Katrine, and 189 at Gorbals. It is the r almost exactly of Manchester and Liverpool, within three days the same as at Dublin, the being measured at five rain gauges, which are sp over the district, and which show very nearly actual mean rain. The rainfall in the Welsh dis was 9·2 inches; the rainfall at Manchester w inches. Taking the mean rain of all the places M chester, Liverpool, Dublin, Loch Katrine, and Gor it was 10·8 inches. Deducting Liverpool, which s to be an exceptional case, and which certainly does represent anything like the drainage ground of Welsh district, the mean rain was 10⅛ inches. mean produce from each 1,000 acres from all t places, was ·949 of a cubic foot per second, omitting Liverpool for the cause I have before na it was 1·087 cubic feet per second. Therefore in table which the Commissioners have before the have taken the produce of the Welsh district at a c foot per second for each 1,000 acres, which is about the $\frac{5}{100}$th part of a foot per second more the mean of all the districts, and about $\frac{1}{10}$th of a per second less than the mean, omitting Liverp Then allowing for that amount of water comin the ground, we could have supplied 350,000,000 lons of water per day from the Welsh district, w is equal to 41½ inches of rainfall in the year. I summed it up shortly in this table:

METROPOLIS WATER SUPPLY.—WELSH SCHEM

THE drought of 1868 only lasted about 120 days b ning at the end of March and ending early in August assuming it to have lasted for 150 days as in Manche or as the mean of Manchester, Dublin, and Liverpool result would have been as follows:—

The yield of the rain and springs on the average of M chester, Liverpool, Dublin, Loch Katrine, and Gorbals ·949 cubic feet per second from each 1,000 acres. Omit Liverpool as showing an exceptional return, the mean 1·087 cubic feet per second per 1,000 acres.

We may, therefore, assume 1 cubic foot for Wale 540,000 gallons per day from each 1,000 acres of collec ground.

	Gallons per
Rain and springs from 130,000 acres at 540,000 gallons per 1,000 acres per day	70,200,000
Store in reservoirs in the hills 6,709,550,552 cubic feet ÷ 150 days=	279,000,000
	349,200,000
Deduct for compensation to rivers at the rate of 9 ins. of available rain per annum	73,028,000
Leaves for the Metropolis	276,172,000

If the quantity to be stored in the service reservoirs Stanmore, be added viz. 772,500,000 cubic feet, the t storage will be 7,482,000,000 cubic feet and the result be as follows:

	Gallons per
Gross storage in reservoirs, 7,482,000,000 cubic feet ÷ 150 days=	312,000,000
Produce of rain and springs	70,200,000
	382,200,000
Deduct compensation to rivers	73,028,000
Leaves for City for 150 days of drought	309,172,000

Or, taking the supply to the City at 230,000,000 gallons per day, the quantity on which the calculations presented to the Commission have been based, and the compensation to the rivers at 73,000,000 equal together to 303,000,000 gallons per day, there would be left in store at the end of a drought of 150 days 1,117,550,552 cubic feet in the reservoirs in the hills, and 772,500,000 cubic feet in the service reservoirs near Stanmore, together 1,890,000,000 cubic feet. This, allowing for the produce of the streams, is equal to a further provision for a full supply both to the City and to the rivers of 47 days; showing that the scheme as laid out is equal to a provision for 197 days of such a drought as occurred in this year, 1868, being about 50 days longer than it actually lasted.

Taking the Welsh scheme, the drought of 1868 only lasted about 120 days, beginning at the end of March, and ending early in August, but assuming it to have lasted for 150 days as in Manchester (I find that it lasted 144) or as the mean of Manchester, Dublin, and Liverpool, the result would have been as follows: The yield of the rain and the springs on the average of Manchester, Liverpool, Dublin, Loch Katrine, and Gorbals, was ·949 of a cubic foot per second from each 1,000 acres. Omitting Liverpool, as showing an exceptional return, the mean was 1·087 cubic feet per second per 1,000 acres. We may therefore assume one cubic foot for Wales, or 540,000 gallons per day, from each 1,000 acres of collecting ground. The rain and springs from 130,000 acres at 540,000 gallons per 1,000 acres per day, gives 70,200,000 gallons per day. The store in reservoirs would be 6,709,550,552 cubic feet, which, divided by 150 days, gives 279,000,000 gallons per day, making together 349,200,000 gallons per day. Deducting for compensation to rivers at the rate of nine inches of available rain per annum, 73,000,000 gallons, you would have left for the Metropolis during the drought of 1868, according to the provision laid down in the scheme which I have had the honour of presenting to you, 276,000,000 gallons per day, or, taking the supply to the city of 230,000,000 gallons per day the quantity on which the calculations presented to the Commission have been based, and the compensation to the rivers at 73,000,000 equal together to 303,000,000 gallons per day, there would be left in store at the end of a drought of 150 days 1,117,550,552 cubic feet, or 30 days full supply, allowing for the produce of streams making a total provision for 180 days. That is as I laid the scheme before you, when I merely assumed 120, or at most 140 days provision, but it turns out by the experience of the drought of 1868 to be a provision for 180 days of full supply, and this is without including the Stanmore service reservoirs.

J. F. Bateman, Esq.

9 Dec. 1868.

7424. Then we are to understand that supposing a like drought of 150 days should take place, having regard to the provision which you have made in your Welsh scheme, you would still have 30 days supply plus the consumption during the drought?—Yes, left in store, that is to say, the streams would yield, and the storage would give together a full supply for 30 days beyond the 150. If you will be kind enough to turn to my evidence of the 5th of March in this year, at page 6, you will find some calculations as to what I believed I could safely say that the scheme would be equal to, and I was very careful not to overstate that nor to over-estimate anything. You will find that I have only allowed, as the produce of the streams during 120 days or 140 days, 30,000,000 gallons if the drought lasted for 120 days only, and only 25,000,000 gallons per day as the produce of the streams if the drought lasted 140 days. I have shown, I think, upon evidence which cannot be doubted, that instead of its being 30,000,000 or 25,000,000 it would in fact be 70,000,000 throughout 150 days, or probably more than 70,000,000 throughout a drought of 180 days, so that I certainly have under estimated the quantity of water which my district would yield by 35,000,000 or 40,000,000 gallons as the produce of the streams. I merely draw the attention of the Commission to that in order to show that in that case, and in every other I hope, I have been careful not to make an over statement. I will merely supplement my evidence by giving you the rainfall for the first 10 months of 1868, during the droughts which occurred at Loch Katrine and Gorbals, at Manchester, at Liverpool, at Dublin, and in Wales, showing the total amount of rainfall at each of those places, and the rainfall which occurred during the period of drought. (See p. 474.)

I may draw your attention, perhaps, to this. If you take Dublin and Wales the average rain at Dublin was very nearly the average rain in Wales during the period of drought, and almost exactly the average rain in Manchester. In Manchester you will find the rain put down rather less than I have taken it in the evidence which I have given, because those gauges are valley gauges; they do not represent the full amount of rain falling upon the whole of the drainage ground, and I have added a little in order to bring it up to what I believe to be nearly the mean. I will also put in a table of the rainfall in the Snowdonian Range, as it is called, at places not far distant from the district which I have brought under your notice, showing the rainfall of the various places there, and the elevation above the sea.

RAINFALL in the SNOWDONIAN RANGE, 1868.

The droughts in the respective districts extended as follows:—Loch Katrine, from 30th May to 8th August=70 days; Manchester, from 28th April to 24th September=150 days; Liverpool, from 28th April to 6th October=161 days; and the rainfall given in the Second Table is for these periods at the several places,

Commission upon that subject. There is one other thing which I have prepared if the Commission would like to have it, that is, a table showing the average daily quantity of water supplied by the London water companies during 1866, 1867, and 1868, up to the end of October, showing the increase which has taken place; it is compiled from the Registrar General's returns.

J. F. Bateman, Esq.

9 Dec. 1868.

TABLE, showing the average daily Quantity of Water supplied by the London Water Companies during the Years 1866 and 1867, and the 10 Months ending October 31st 1868, and during the Summer Months of June, July, August, and September in each Year, compiled from the Returns made to the Registrar-General.

There is only one observation which I wish to make upon this table, and that is that in 1866 the average quantity supplied by the East London Water Company was 20,702,000 gallons per day; in 1867, 20,094,000; and in 1868, 18,450,000. During the month of August in this year the East London company was only delivering about three-fourths of the quantity of water which it ought to have delivered, owing to absolute scarcity; it was not in the river Lee to deliver. The normal delivery of the company is 19,950,000 gallons in summer, as it was in June and July; but in August it only delivered 15,848,000, in September only 18,100,000, and in October only 18,033,000, so that owing to that deficiency in the water supply the increased consumption of 1868 over 1867 has not been quite as much as it would have been had the East London company been capable of giving a full supply. The increase of 1867 over 1866 was 4,200,000 gallons per day during the months of June, July, August, and September, and upon the whole year 3,700,000 gallons per diem. The increase in 1868 over 1867 in the four months June, July, August, and September was 3,514,000 gallons per diem, but had the East London company been capable of delivering its full quantity, it would have been upon the summer months 4,500,000 gallons per day, and upon the whole year about 3,000,000 gallons per diem.

7425. Then the increase was less in 1868 than in 1867?—Yes, slightly.

7426. Then having regard to the progressive increase of former years, supposing that the supply had been equal to the demand, what would have been the deficiency?—The increase would have been about the same. I have handed in those tables because they bear upon my former evidence, as showing what I estimated to be the increase. Had there been no deficiency in the East London delivery, the figures which I gave before would have corresponded with the facts. I think I have now given the Commission all the information which I wish to lay before them.

7427. (*Mr. Prestwich.*) With regard to the quantity of water supplied to Manchester during the drought of 1868, you stated that the balance left in store on the 25th of September, after 150 days drought, was 435,000,000 gallons, but that during 45 days there was a diminished quantity supplied to the mills, and further, that during 52 days the water was shut off at night. Supposing the supplies to the mills and to the town to have been continued to their full amount during this period, have you calculated what would have been the quantity in store?—We should have exhausted our store, and we should have been perhaps, something like 200,000,000 or 300,000,000 gallons deficient.

J. F. Bateman, Esq.

9 Dec. 1868.

7428. You are preparing larger storage, are you not?—Yes. Our works are now very far from being complete, but we are constructing two new large reservoirs; and we have a third reservoir which we have never been able to fill owing to the bad foundation, which, as soon as the two others are completed, we shall restore, and that will nearly double our storage at once. It is a mere question of storage in Manchester. We have abundance of water, but we are two years behindhand in our works, and we are two years beforehand in the calculated supply. We have been extending the supplies to the outlying districts so much that, while we have been falling behind in our engineering operations, we have been going too fast in the supply of water to the district, and therefore the two causes together put us into this position this year.

7429. How many days storage have you at Manchester now?—The drought lasted 150 days. I think we went on for 105 days without any diminution to the mills, and for 98 days before we shut off the water at night at Manchester, and we had then a very considerable quantity of water in store. Therefore, for something like 120 or 130 days we could have given a full supply to Manchester and to the mills had the drought lasted no longer, but it did last 150 days.

7430. (*Mr. Harrison.*) What are the total cubic contents of your storage at Manchester?—About 2,736,000,000 gallons I believe are the cubic contents of the storage which we now have, and were so at the commencement of the drought of 1868, and we are now increasing it by about 1,800,000,000 gallons.

7431. (*Mr. Prestwich.*) In those diagrams which you have produced showing the delivery of water during the continuance of the drought, the effect of a fall of rain during this period of drought is shown almost immediately is it not by the rise?—Yes.

7432. There were many days, were there not, during which no rain fell at all?—Yes.

7433. Therefore during that period the flow would depend, would it not, entirely upon springs?—Yes, entirely. There is a little variation, but during the whole of June, and down to early in August, the streams were almost wholly spring water.

7434. Therefore this delivery from springs would depend upon the rain which fell during the previous winter?—That would depend upon the geological formation. It would be so if it was upon chalk or sand, but not upon granite.

7435. Or upon millstone grit?—No doubt it does to some extent, but I do not think it does much in the millstone grit, and it does very little in the silurian. The springs fall very quickly indeed in the silurian, and very quickly in the granite.

7435. Therefore the harder the rock surface the less would be the delivery from springs?—Yes, no doubt.

7436. And therefore this delivery would depend very much upon the amount of rain which fell during the preceding winter?—I think not very much. It would, no doubt, depend upon the amount of rain which fell during the preceding period; but you see immediately after rain it falls off very rapidly. The diagram which I have placed before the Commission is a very different one from that which would be shown in a chalk district, or in a sand district, because a chalk district, or a sand district, like the greensands of Surrey, delivers its water out more slowly, and a diagram would not show these sudden rises and falls.

7437. If there was no rain, the supply must have been derived from the rain of the preceding period?—Yes; in the Silurian district of the Dublin waterworks, for instance, which is a district very nearly corresponding with the Welsh district, both geologically and physically, you will find that the produce was 1·3 cubic foot per second from each 1,000 acres during the drought of 141 days. In Loch Katrine, where the springs are almost nothing in dry weather, the ground is not only very steep, but there is only a small portion of flat top covered with peat. The rock is so hard, that in making our tunnels there we had to take water down to lubricate the drill holes for the miners. The water cannot get in, and therefore there is none to come out. During the months of extreme drought, of June and July, the produce of the Loch Katrine district was ·84 of a cubic foot per second from each thousand acres. I had the rivers measured in Wales at the extremity of the drought in July, and the produce there was certainly very small. It was then ·13 of a cubic foot per second. At the extreme of the drought in the millstone grit in the same period the general result was about ·25 or ·3; so that at the extreme drought the silurian district yielded about one-half what the millstone grit did.

7438. Would not that depend almost upon the geological character of the ground, because the harder the rock the less is the delivery, and also upon the inclination?—Yes, unless you go to bare hill sides, where the water comes down as from a roof, and there is nothing to absorb it, and you get every drop of water in the valleys. You have to take it as a compound question; a flat district yields water very slowly, an absorbent district yields it still more slowly. A district composed as Wales, partly of steep hill sides, and partly of gentle undulating slopes, would be equal to the mean between Dublin and Manchester. I think, taking Dublin and Manchester together, the Dublin formation being almost the same as that of the Welsh district, both being Silurian, both being very similarly mountainous, rising to very much the same height, and taking the Manchester district, which rises from 1,900 feet to 2,000 feet, with very steep slopes and flat tops, those afford a very fair sample of the geological and physical conditions of the district forming the source of the Severn.

7439. Do you find in the Manchester district where the water comes from off the millstone grit area, that it gives a larger delivery than the silurian area of Glasgow?—No, it does not, it gives a smaller one than Loch Katrine, for during the 70 days when Loch Katrine was delivering ·839 cubic feet per second, Manchester was delivering only ·5114.

7440. (*Mr. Harrison.*) What was the rainfall during this period?—It was 4·40 inches at Loch Katrine. The drought in Loch Katrine commenced on May the 31st, and ended August the 8th. Therefore it was just through the months of June and July. The mean produce of the district was ·839 of a cubic foot per second from each thousand acres, whereas the mean produce of the Manchester district during the same period was ·5114 only. From the 1st of June to the 28th of June it was ·612, from the 29th of June to the 3d of August, which together cover exactly the same period, it was ·43, and the mean of these is ·56 against ·84, so that the Loch Katrine district really yielded a larger quantity of water than the millstone grit district. The rainfall in Loch Katrine was 4·4 inches, whereas the rainfall in Manchester during that period was only about 1¼ inches.

7441. Can you give us the rainfall for the preceding winter in each of those two districts?—The rainfalls of 1866 and 1867 were both very considerable. I think that the figures will be found in some of the papers which I have put in. In Manchester, in January and February it was about 4½, and about 7½ in March. In Glasgow in some places it was 17 inches in January, 17·4 inches in February, and 10 inches in March, and in Wales it was in February in some parts 10 inches, 12 inches, 13 inches, 11 inches, 17 inches, and in March 11 inches, 9 inches, and 7 inches, so that the Welsh district more nearly approximates to the Loch Katrine district. With regard to a question put to me by Mr. Prestwich I have been working out what was the rainfall during the months of June and July, which was the only period during which the drought extended in the Loch Katrine district, and this was the state of things. In Liverpool in those

months the rainfall was 1·42, at Halifax in the streams to which the diagrams which I have produced refer, it was ·6 of an inch, in Manchester 1·28, in Wales 1·6, in Loch Katrine 4·4, in Dublin 3·54, and I see that in Loch Katrine which is the only one I have worked out as to the exact quantity of water flowing off the ground in those months, in 70 days the produce was equal to 1·39 inches in depth flowing off the ground, so that 3 inches out of $4\frac{1}{2}$ inches were absorbed and lost.

7442. (*Chairman.*) Have you taken any measurements of the Thames this year?—I have had the river measured twice this year in order to get the driest volume. I had it measured in July, but then the river was so full of weeds that it was excessively difficult to get anything like an accurate result, but according to the best approximation that we could make, the volume was about 370,000,000 gallons per day at the same place that I measured at in 1865.

7443. Was the measurement made above the point where the supply is taken by the water companies?— Yes. I had it measured again just after the weather broke in September. I was away from home at the time of the end of the drought, and my people were most of them holiday-making, therefore I did not catch it just at the end of the drought. My impression was that it was never so low as it was in the autumn of 1865.* *J. F. Bateman, Esq.* 9 Dec. 1868.

*16, Great George Street, Westminster,
December 9th 1868.

My dear Sir,

I find that the volume in the river Thames fluctuated so much when I sent to have it measured in September last, from recent rainfall, that the attempt had to be abandoned. In July it measured, as I stated, about 370,000,000 gallons per day, but the river was so choked by weeds that the measurement could not be relied upon as accurate.

Yours very truly,
J. F. Bateman.

W. Pole, Esq.,
Water Supply Commission.

The witness withdrew.

Nathaniel Beardmore, Esq., further examined. *N. Beardmore, Esq.*

7444. (*Chairman.*) You are desirous, are you not, of correcting a table which you put in at the time you gave your former evidence?—There is a slight error in the figures, and therefore I propose to send them in corrected, with the flow and rainfall up to the end of the present year, so as to give the information complete in one view. (*The tables were subsequently sent in by the witness as follows:*)

Estimated Flow of Rivers Lee and Thames.

Mean Annual Flow for 1850 to 1868, including Water Companies' Supply.

Means -	5,050	45·2	·90	8·7	48,108	431·2	·99	9·77	9·75

7445. Have you anything further to state as to your experience of the river Lee during the year 1868?—1868 has not been such a drought with regard to the chalk rivers as might have been with the intense heat that we had. The heat affected the land springs, and no doubt took them almost away, and in many cases diminished the volume from the springs from the drift above the chalk, but the deep chalk springs have been in very fair volume this year, both on the Lee and on the Thames.

It will be seen by the tables that the heat and drought of 1868 has not reduced the stream to as low a volume as in some other dry years. This is because the chalk springs are too deep to be immediately affected by hot weather, and the supply being mainly governed by the effective flow of the two previous years, both of which were above an average.

7446. Would not the long drought of 1868 require a heavier fall of rain in 1869 to recoup the store in the chalk?—The drought has not been to that excessive degree, for it did not extend beyond the end of July, the rainfall of August, September, and October being rather liberal, so that I think we are insured for next year.*

7447. I mean if this drain were to go on should we not observe in the chalk springs the effect of the drought for some time to come?—Yes, if we have a very dry winter, there may be a low flow next summer; but we have had a full share of rain since August, when the drought broke up.

7448. But you have not had a sufficient fall yet, have you, to make up for the long drought?—I think that the rain of the last day or two will bring us up to a fair supply during the winter; but up to the 5th instant, even when there had been a good deal of heavy rain, the river fell to its normal summer volume within a day or two, owing to the general exhaustion of the water in the upper strata.

7449. Having regard to the amount of rain that has already fallen in the year 1868, is there in your judgment any reason to alter the previous figures which you gave to the Commission as to the net result of the rainfall in the area of the river Lee?—Not at all. I have mentioned in my statement that our real minimum was in 1864, 1865, and 1859, whi were all low years taking the average of the fo summer months. The figures are so near to ea other owing to the large area over which the rs falls. The water has to percolate deep subterrane strata of chalk, and it appears (of course I am spea ing now from 19 years' gaugings) to average itself to a low point at which surface temperature or te porary drought has not much influence. I find th the upper springs fail completely after long d periods; and this reduces the general volume of t river. The lower springs do not vary much in th mean supply; they are very permanent indeed; t the difference of their volume between May a November is frequently very considerable.

The subjoined table of mean flow of June, Ju August, and September, will show that the fl during the minimum period of the year in a riv draining chalk and overlaying tertiaries, is govern by the supply of the previous year and winter. T flow of March and April is here given for comparis with that of the following summer months, and it w be seen that the test of drought has been one or t previous low years; for instance, out of a wh period of 19 years there have been five summers low water supply, viz., 1855, 1859, 1864, 1865, a 1868. According to the deficiency of rain and the he of the summer, the year 1858 should have been l (the whole year's rainfall being only 20·86 inche whereas it had a summer flow of 20 per cent. mo than that of 1868. This is caused by the lar volume of the year 1857, which was carried throu the winter, as will be indicated by the flow of Mar and April of 1858. The low summer of 1858 w followed by a winter so dry as to reduce the flow the following March and April to an extremely lo average for those months. This is one of the fac showing that the period required to fill the subterrane supply to deep springs in the chalk extends over ma months, and that a long period is necessary for the exhaustion.* The summer of 1859, then, is conspicuo as having a small flow both in the Lee and the Thame

* This evidence was given on the 9th December, up to which time the volume of the river had not much increased, but heavy and continuous rains set in on the 15th of the same month which produced heavy floods on the Lee, and still more so on the Thames. The rainfall at Feilde's Weir on the Lee, for December, amounted to 4·80 inches, and at the Radcliffe Observatory, Oxford, to 4·12 inches, which fell during 24 days at each place.

* The summer and autumn of the year 1858 were so dry over the mountainous district of Central Europe that the flow the Danube, the Rhine, the Elbe, the Weser, and other riv was low beyond any precedent. In the Danube foundations an ancient Roman bridge were uncovered that had passed o of memory of man, and was only known of in ancient class records. My friend, Herr Michaelis, Chief Engineer of t Water Staff of Westphalia, informs me that three years elaps from 1857–8 before the deep springs were filled to the norm volume.

ough the rainfall was 12·3 inches; 1864 had a trifle less flow, although the rainfall was only 5·7 inches. The following tables will explain these peculiarities:—

AN SUMMER FLOW of the RIVER LEE, from 1850 o 1868, with the comparative Mean Flow of March nd April in the same Years.

Years.	Mean Flow of June, July, August, and September.	Mean Flow of the previous March and April.	
		March.	April.
	Cubic ft. per minute.	C. ft. per min.	C. ft. per min.
1850	7,753	11,413	15,351

Mean -	10,209	25·11	25·91	32·68

7450. Then speaking of the area of the chalk, there nothing in the experience of 1868 seriously to disange the calculations of the water supply?—Not all. It is the other way, it confirms them. I think, in the case of all things in nature extending over ong series of years, we should get practically to a ry close average.

7451. Is there any other point to which you desire to l the attention of the Commission?—No, excepting night observe that the larger the area of such a disct as this, the better you can ensure a water pply.

The Thames has been decidedly giving a good flow s autumn, owing to its very large area, and the cident that in August and September there really as a very considerable amount of rain; viz., in ugust there were 3·34 inches of rain; and in eptember, 3·98. As to the general question of water pply, the practical conclusion I have come to is that, r large cities, it is unsafe to rely upon small areas r a liberal supply of water, especially where the argin for quantity and for due purity should be conderable. Cretaceous and oolite areas have a pre-emient advantage in their springs being deep, whereby mense slowness of filtration is obtained, and so at practically their rivers are the purest when putrection is in highest energy, and when any foul ntributions are at their minimum. During many onths of the hot weather of 1868 no surface flow eached the main body of the Lee or the Thames, the w exceptions being solely due to places where artiial water supply with sewers had been applied. In ct the drought and heat were so great that from une to October all ditches were dried up, and no ain even sufficed to moisten the ditches of the lowest arshes until the 23d of November. The water of ie Lee never showed a trace of turbidity from the 9th of March until the 23d of November, when a fall f nearly an inch of rain on the previous day developed slight trace of turbidity in the water, but up to the th instant—December—no real flood water has own itself.

7452. Is that due to the chalk formation?—I am peaking of rain falling on a large permeable area, lthough the direct effect of that quantity of rain has een but small, yet still it has refreshed the springs, nd the Thames has a very good flow this autumn.

7453. Is that flow of the Thames due to the chalk formation in the upper part?—The upper part of the Thames flows from the oolite, but where you have that formation there is a greater rainfall, so that the flow is supplemented, although you have not got such good storing power. At the Thames head the beds are liable after a drought to lose their water much sooner than the lower beds of the chalk; in fact they are higher springs altogether, and they naturally fall off more.

7454. (*Mr. Prestwich.*) Can you state to the Commission what was the flow of the Lee during the period of drought?—The lowest actual flow of the Lee was in July, and the mean of that month was 4,726 cubic feet per minute.

7455. Can you tell us what rainfall that is equal to?—It amounts to a depth of ·34 inch run off during the month of July, or ·29 cubic feet per second per 1,000 acres. The river Beane where it joins the Lee at Hertford has an area of 71¼ square miles; the flow during the drought of 1868 was ·415 of a cubic foot per second per 1,000 acres.

7456. (*Colonel Harness.*) Do your observations include any records of the position of the water line at different times in the chalk got by gauging wells?—No; I only know this, that on the Lee, whenever we get below 5,500 cubic feet per minute at Feilde's weir, the highest springs begin to fall off.

7457. What is the level of the highest springs in the Lee?—The largest commence above Hatfield, about 180 feet above Trinity high-water mark; below this springs are numerous. One is Woolmer's spring, between Hatfield and Hertford; it is a very beautiful spring, but still it is high, viz., 144 feet above Trinity, and it always fails in low years. It has failed in 1855, 1859, 1863, 1864, 1865, and 1868. The lower and more permanent springs from the chalk are Chadwell, near Ware, at 97 feet; Amwell at 86 feet, and Hoddesdon mill springs at 80 feet above Trinity high water. Below Hoddesdon there is a fault, and the chalk becomes overlaid by the London clay, &c., and there is no water direct from the chalk except by means of borings, which give a good deal of water as far down as Tottenham. The Lee is canalised for a great portion of its length away from the water companies' channels, and it has not been short of water

N. Beardmore, Esq.

9 Dec. 1868.

this year. Mr. Bateman has mentioned something about the East London Waterworks shortening their supply of water; I do not think it can have been owing to the want of water, because we have always had a good head. They have been doing very large work on the Lee, and there may have been some other caus that I do not know of.

The witness withdrew.

J. Taylor, Esq.

JOHN TAYLOR, Esq., examined.

7458. (*Chairman.*) You are a civil engineer, and engaged, are you not, with Mr. Simpson?—Yes, I have been engaged for many years with him. He is engineer to the Chelsea and Lambeth Waterworks Company and he has carried out a large number of other waterworks throughout the kingdom.

7459. You are desirous on his behalf as well as your own, are you not, to put in some documents as to you experience during this last year of 1868 with regard t the rainfall and the condition of your supply?—I hav prepared a table showing the average daily quantit supplied by the metropolitan water companies durin the summer months of the years 1867 and 1868, a follows, which I desire to put in:

RETURN of the AVERAGE DAILY QUANTITY of WATER, in GALLONS, supplied by the METROPOLITAN WATE COMPANIES during the Summer Months of the Years 1867 and 1868.

Companies.	May.	June.	July.	August.	September.	October.

Per cent. of increase	3·52	2·66	4·60	2·82	3·22	1·93

November 1868.

7460. Have you a report made by you to the chairmen and directors of the London water companies?—Yes.

7461. Was that made by the direction of the several water companies of the metropolis, or of the companies of which Mr. Simpson is engineer?—By direction of all the water companies of the metropolis.

7462. Did you make this report to the directors of all the companies?—To the chairmen. The chairmen have formed themselves into a board for the purposes of this inquiry, and they requested me to visit several towns and report the results of gravitation water supplies.

7463. In pursuance of their direction did you visit several towns for the purpose of ascertaining the effect of the short supply of rain during the year 1868 upon the supply of water to those several towns?—I did; and the results of that inquiry are given in a second report. I may state that in May last they requested me to visit various towns in England to procure evidence with reference to the general results of gravitation water supplies in large towns. That I did, and the result of that inquiry is embodied in my first report, dated June the 9th.

7464. But you made a subsequent report, dated November 1868, which would be after the short supply of rain this year?—Yes. Seeing the drought this year, which took place after this first report was made, the chairmen requested me again to go to many towns and ascertain the effect of the drought upon those towns. And the result of that inquiry is embodied in the second report.

7465. Have you any tabulated return which would give the substance of those long reports?—No I have not. I will hand in the first report dated June the 9th, 1868, (*delivering in the same. Vide* Appendix, BB.) I may state that the first report was made on the general appearance of the water supplies by gravitation to towns, anticipating as it were a drought, and foreshadowing what might be the results of a drought of this sort. The results of the drought of this year are given in the report dated November 1868, (*delivering in the same. Vide* Appendix, BC.)

7466. Are those reports the result of your own observation, and of information which you obtained from the several engineers and officers in charge of local works?—They are.

7467. They are made for the purpose of meeting the other schemes which have been proposed?—They are a statement of facts as regards the water supplies to the towns therein mentioned, as far as I could get the facts. I believe them to be substantially correct. I will not be certain that every figure is correct, but substantially it is so.

7468. (*Colonel Harness.*) Are there any facts in these reports which could be disputed by the authorities in those places?—None whatever, to my knowledge. In the second report are given public notices which have been issued referring to the drought and the shutting off of the water in the different towns and the short supplies. Those are public documents, which no one can dispute.

7469. (*Chairman.*) Were your instructions to collect information as to the existing facts? My instructions for the second report were to go round and collect the facts as regards the effects of the drought this year upon those towns.

7470. Without reference to any proposed scheme to supply water to the metropolis?—Yes, without reference to any proposed scheme, but to lay before you the facts with regard to the drought.

7471. And you have given to the directors the results of your experience and observation, and of information obtained from the parties?—I have done so.

7472. Do you also put in a tabular statement of the volume of water in the river Thames measured at various times opposite the Lambeth and Chelsea Water Companies' Works above Kingston?—Yes.

7473. Is that measured at the point where Mr. Simpson has been for some time taking gaugings and has made a careful section of the river?—Yes, it is measured just opposite the Lambeth and Chelsea Waterworks, at the point where they abstract the water. These are the results of the gaugings from time to time as they have been recorded.

7474. And the smallest quantity appears to be 395,000,000 gallons, on the 23d July 1858?—Yes.

TABULAR STATEMENT of the Volume of Water in the River Thames, measured at various times opposite the Lambeth and Chelsea Water Companies' Works above Kingston.

4th December 1868.

7475. (*Colonel Harness.*) Between 1854 and 1858, did you change the place of gauging?—It was a little up the river originally, the first ones were above where the Lambeth supply is taken.

7476. Then you went to an intermediate point, below the supply of some of the companies, but above others?—The latter gaugings were taken abreast the lowest of the five companies, which is the Chelsea Company.

7477. Then the last of all is without the whole of the water?—It may be assumed that it is without the water that is taken by the companies.

7478. Will you tell us how you gauged it?—We selected a portion of the river that is pretty straight and equal in the channel, and took a number of cross-sections measuring by a rope the width of the river, and sounding the depths at stated intervals, by which means we get a cross-section of the river, and half a dozen such sections over the portion of the river that we are going to measure are sufficient to obtain an average sectional area, and then ascertaining the velocity of flow of water by experiment and multiplying it into the area, the quantity is arrived at.

7479. (*Chairman.*) Then are the Commission to understand that the table which you have put in is a table shewing the quantity of water flowing past the point where the gauging is taken on the respective days mentioned in this report, and that it is not the minimum flow?—It is the flow at the periods that these were taken at, but they are generally speaking the dry weather flow of the time at which they were taken, excepting the last one.

7480. Do you keep a daily register, or how often are those gaugings taken?—We keep a daily register of the height of the water, and have done so for many years past, but the guagings of the water have only been taken at those periods mentioned.

7481. You have a section and then you have to take the velocity, and that will give you the result?—We take a number of cross-sections and take the mean of those sections; after that we take the velocity of the surface flow, and by a great number of observations we get the mean of that; and then by a certain rule we reduce it to what is called the mean velocity of the river, and multiplying one by the other will give the contents.

7482. Can you tell the minimum flow of the Thames for any given year, taking the year 1867, for example?—No, I have not it for the year 1867. We take the depths, as I stated, daily, but that does not always give the flow.

7483. You may have 1,400,000,000 or 1,500,000,000, or you may have 350,000,000, it depends entirely, does it not, upon when the gaugings were taken?—Yes. But I must explain that these were all taken as the dry weather yield of the year, in which they were made, they were taken at those periods because they were considered dry periods.

7484. Take September 16th, how are we or the readers of your report to understand that the gauging on the 16th of September was not a gauging after a fall of rain on the previous day, or within the previous 48 hours?—I have given them in as the dry weather gaugings, and therefore, of course, that would infer the absence of any considerable rain to affect the river. A considerable fall of rain would immediately produce a very much larger quantity than any of the quantities stated here, excepting the last one.

7485. (*Mr. Harrison.*) Taking the 20th of October 1868, the table shows here a flow of 554,000,000 gallons, is that the smallest flow that has taken place during the whole of the year 1868?—No, it is not. We did not measure the flow during the minimum period. I had no order to measure it, and it was not measured, but I can estimate the flow within very narrow limits during the excessive drought of this year.

7486. (*Colonel Harness.*) From what data would you estimate it?—In the first place we take the depths every day, and they are registered in a book, and from those depths we can always arrive at what the cross-sectional area of the river was at any time, then by the observations of the parties who are daily upon the works I have ascertained that the flow of the stream was somewhere about 5 inches per second.

7487. (*Mr. Harrison.*) That would vary, would it not, with the quantity of water in the river?—I am speaking now of the minimum time which occurred about the end of August and the beginning of

* Exclusive of the quantity abstracted at Hampton by the Grand Junction, West Middlesex, and Southwark and Vauxhall Companies.

† Exclusive of the quantity abstracted by the five Thames Companies.

J. Taylor, Esq.
9 Dec. 1868.

September, that would give 270,000,000 gallons, and from the spot that it was measured at there would be the five companies water which was not included in it.

7488. (*Chairman.*) Can you state what was the minimum flow of the Thames at that point in the years 1866, 1867, and 1868?—I am going to give it in the year 1868, as near as I can estimate it. I cannot give it for the three years, it would be 270,000,000 gallons, apart from about 50,000,000, gallons which the five companies were taking above where the measurement was made, that would be 320,000,000 gallons. That, I believe, is as low as anything that the Thames has been since the companies' works were constructed.

7489. Is that the lowest amount as registered by you?—We have had no measurement so low as that, this is an estimated measurement, and it is the lowest quantity. With regard to the quantity in cubic feet per 1,000 acres, the measurement of the Thames this year, would reduce it down to something like a quarter of a cubic foot per 1,000 acres. I may mention that yesterday I obtained a good deal of information about the River Mole, which supplies a considerable volume of water to the Thames above the Chelsea and Lambeth waterworks. The River Mole has a drainage area of about 130,000 acres, and the minimum flow was reduced to about 20,000,000 gallons from that area, which would be about ·28 of a cubic foot per 1,000 acres. I will also beg to hand in the following table, which I think may be interesting to the Commission:—

TABULAR STATEMENT of the minimum flow of water from various drainage areas.

River.	Year and Season.	Drainage Area. — Acres.	Quantity flowing off per day. — Gallons.	Quantity per 1,000 Acres in Cubic feet
Dee at Woodend (Aberdeen) -	Sept. 1868	332,160	120 millions	·66
Thames at Ditton -	Augt. 1868	2,368,000	320 „	·25
Mole at junction with the Thames -	Augt. 1868	130,000	20 „	·28
Thames at Staines -	Ordinary summer discharge (from Mr. Beardmore's Hydrology.)	1,975,000	360 „	·33

10th December 1868.

The witness withdrew.

Adjourned to to-morrow at 12 o'clock.

Thursday, 10th December 1868.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Alderman Sir BENJAMIN PHILLIPS.
Colonel HARNESS, C.B.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

THOMAS HAWKSLEY, Esq., further examined.

T. Hawksley, Esq.
10 Dec. 1868.

7490. (*Chairman.*) The object of the Commission is to ascertain what has been the result of your experience during the year 1868; whether the diminished quantity of rainfall has seriously affected any waterworks with which you are connected, or of which you have any knowledge, and if so, to what extent? Will you have the goodness to furnish us with any information that you have upon the subject?—The diminution in the rainfall has affected the gravitation waterworks very seriously, and the towns which are dependent upon them, but probably not so seriously as the drought of 1865; because the drought of 1868, though more intense, set in at a later period of the summer; and there was this remarkable difference between the two cases, that in the case of the year 1865, I think it was, a great number of the reservoirs had never been filled in the preceding winter; and consequently the drought of the succeeding summer was super-imposed, so to speak, on a drought which continued through a portion of the previous summer, and also to a certain extent through the previous winter. In order to illustrate that part of the subject, that being really the most important one, I produce the diagrams which are kept by the Leicester Waterworks Company of the state of their large storage reservoir, the particulars of which I will shortly give you (*producing some diagrams.*) These diagrams show the state of the reservoir every day. In the latter end of September 1868 the rain returned; but the ground was so dry, in consequence of the long continuance of the drought, that a month ago the rain had not penetrated 18 inches into the ground, and the ground was dusty at a depth of 18 inches, for I have had it opened in various places for the purpose of ascertaining what were the facts. As I say, the ground was as dry and dusty at a depth of 18 inches as you could conceive it to be in the month of July, the rain not having penetrated. And this is the case in various parts of the kingdom where I have tried that experiment.

7491. Have you tried it this month?—I have tried it within a month, but not this month. What I am about to point out is this. In the year 1864 we had in the spring of the year, full reservoirs overflowing and water going to waste to the sea. It then became dry, and the Leicester reservoir descended, as you see by the diagram, till it became almost exhausted, and there was great apprehension that it would be entirely exhausted. This was the year prior to what is called the water famine. I do not suppose that there was more than one tenth of its volume left. These diagrams are kept by the company themselves, and having sent a telegram, I have received them this morning within the last hour; and I thought that they were so important for the purpose of the Commission that I have procured them for you.

7492. Are we to understand that you attribute the deficiency of supply in the year 1865 in a great measure to the small quantity of rain in August, September, October, November, and December of the year 1864?—Yes, and also in January, and part of February 1865. In the next sheet you will see that it continued to descend till the middle of January; then there came some rain, which raised the reservoir a little, but a very little indeed, because it was, so to speak, only like covering the bottom of a wine-glass, so that there was a very little quantity put in. Then it went down again to the end of the month, then there came a flood in February, which raised it with very great rapidity; the flood ceased, and the feed of the reservoir just about balanced the draught upon the reservoir for a week or eight days. Then there came another flood in March, which brought the reservoir up to the point indicated here (*pointing to a diagram*), about 5 feet 8 inches below the overflow. But I ought again to remark upon that, that the quantities of stock in the reservoir are as the cubes of the depths, and therefore that the greater quantity always lies in the upper few feet. The reservoir never filled in that year by a very large amount, and consequently, the drought again setting in, the reservoir was reduced to almost as low as it was in the preceding winter. That reservoir—

and it is important to observe upon that—was made for 240 days storage, and it was nearly exhausted. That is the most important fact which I have to produce; and I have also to state this, that any estimate made upon the duration of a drought, taken from the commencement of the drought to its termination (and I have made that mistake many years ago myself), has been found to be entirely fallacious, because you must add to the drought of the preceding year the number of days of stock which the reservoir fails to fill in the succeeding year, and so on, it may be for two or three years. I dare say there was considerably more than one-third, probably nearly half, the contents of the reservoir contained in its upper portion.

7493. That will depend, will it not, somewhat upon the gathering ground?—Not at all; it is perfectly independent of that.

7494. I mean upon the nature of the springs?—To an insignificant extent—so insignificant that I need not stop to explain it now, but I will explain that very soon.

7495. (*Sir Benjamin Phillips.*) Have the inhabitants any other resources for obtaining water besides this reservoir?—No; but then, as I stated before, this reservoir was made upon the supposition that it ought to contain 240 days of stock. Therefore it never did become exhausted; but it became so nearly exhausted that the company was in great alarm, and notices were put up all over the town, and many means were taken to diminish the waste, and to diminish also the consumption as far as it was possible.

7496. (*Colonel Harness.*) Can you remember what proportion of the average rainfall you have assumed to supply the population?—Put into rainfall I can tell you, but I cannot give it you on the instant. I should say it would be about 9 or 10 inches of the rainfall.

7497. What is the average rainfall?—28 inches, from which we drew off 16 inches, leaving 14.

7498. And you allow 9 inches for your delivery?—Yes, but I should like to be very explicit upon that subject, and to explain the rules which experience has enabled us to come to, and perhaps if the Commission wish to have it now, I may give it at once. We find this from actual experience, that when we make reservoirs of the large capacity which I am about to indicate to you, one-sixth of the whole rainfall goes to the sea; that is to say, the rain continues to come down in wet years when the reservoir is full, and the excess goes over the waste weirs, and of course is lost for ever. I may mention to you that I have for many years been obliged to pay very great attention to this subject, and for my own purposes I have prepared diagrams of the actual facts connected with reservoirs, showing the quantity of water which cannot be retained. First, I will take the case of Greenock, which is a very important case, and gives the result over a great number of years, from 1831 to 1865. I produce that diagram because that is a wet country, and the ground is chiefly whinstone, and therefore is accounted favourable for gravitation works; there is as little loss as may be. The figures on the diagram indicate the inches of rain which fell every year. In those years, namely, the years 1831, 1832, and 1833 to some extent, an enormous quantity of rain fell beyond the average, which could not be stored in the reservoir for use in the succeeding year, for in the next year there was no room scarcely, and you could not put that great area into this little hole (*pointing to the diagram*) to make an average, therefore all that went to the sea and was lost for ever. So the next year the deficiency of gathering was so small when compared with the years of excess, that no reservoir of practical make could have stored that excess; you might write off a little from the top, enough to fill the vacuity, and the rest must have gone to sea.

7499. (*Chairman.*) The years 1836 and 1837 balance each other, do they not?—Yes; the next year is neither sensibly in excess nor defect; the next two years are in defect, but not more than the contents of any reasonably sized reservoir would have supplemented. Then there came an excess, and then in the next year a very serious defect. If the reservoir had been large enough, that excess of former years might have been all stored in order to make good that deficiency, or nearly so. The next year again was near the average, but in the year after, 1844, we come to an enormous defect. The next year that defect was not made good, and the next year again there was another serious defect, and so we go on from time to time. What we find actually is this, that one-sixth of all the rainfall, and we find that from the workings of many reservoirs, is lost. Then in addition to that there is all the evaporation lost. The evaporation here (*pointing to the diagram*) would be about 13 or 14 inches; that would have to be wiped off as a constant quantity from the bottom of the reservoir, and the remainder only is the quantity which is available for the supply. I have also other diagrams for the same place (*producing some other diagrams*) on which you will see marked the quantity lost which could not be stored. The brown part is the quantity which was actually availed of (*describing the same*); 14 inches represent the amount of evaporation which was also lost.

7500. Are we to understand you that 35·91 inches, or nearly 36 inches was actually stored?—Yes, stored and used; it was available for supply, and the loss was the difference.

7501. You have told us the actual net result of the rainfall, can you tell us the average of the rainfall?—The average for the years from 1835 to 1865, inclusive, was 59·89 inches, and the average quantity stored during those years was 35·91 inches; there are many other cases that I might refer to, but the general fact is this, that when a reservoir is proportioned upon the principle which I am about to mention, then the first thing to be done is to ascertain, if it be possible to ascertain it, the average of the rainfall taken over a very large number of years. From that deduct one-sixth, that being the quantity which will inevitably go to the sea and be lost over the waste weir in consequence of excessive rains in wet years, and rain in other years continuing to fall after the reservoir is full.

7502. Supposing the reservoir were made of a capacity equal, or more than equal, to the storing of the whole average quantity of rainfall, would the one-sixth with the same certainty pass over it?—It would not, only such reservoirs are impossible to be made, because the great floods which enter into the average only come once in seven years, or 14 years, or even 20 years. The consequence would be that you would have to make a reservoir which would hold a flood which would happen only once in 20 years, and to make it of a most enormous capacity to distribute it day by day over that 20 years. Now, inasmuch as there are more than 7,000 days in 20 years, you would only get by that daily, which is the object of the supply of water to a town $\frac{1}{7000}$th part of that quantity, whereas the cost of making such a reservoir, even if you could find a situation to do it in, which you could not, would be so enormous that it is utterly impossible to deal with those exceptional cases.

7503. I can understand the objection to making a reservoir of that size, the object of my question was to test the principle, which seems rather an arbitrary one, that one-sixth must necessarily pass off?—It is not abitrary, because it is based upon experience, that experience being reduced to a rule which I think is now so well established that it is impossible to controvert it, which rule I am now about to lay before the Commission. And that being so, with great submission I should rather object to the use of the word arbitrary, because we have ascertained it as a matter of fact. We must have some hard lines, because engineers must proceed upon some data, otherwise calculation would be impossible, and we should all be referred back to what is called judgment, which is the most uncertain guide in the world. The next thing to do is, from the residual quantity to take off the amount of evaporation known to prevail in the districts in hand. It may be a very high and precipitous district, it may be as in the north of England hard ground, or on the other

T. Hawksley, Esq.

10 Dec. 1868.

hand it may be as in the south of England a warmer climate, and flatter land, and so on.

7504. (*Colonel Harness.*) Observations would give you, I presume, the amount of evaporation of a district?—Yes, we know them all, and we can tell with great precision simply by viewing the country what the amount of loss by evaporation is. It amounts rarely to so little as 11 or 12 inches, very commonly upon the hilly grounds it amounts to 13, 14, and 15 inches. In the south of England, and on the flatter grounds and more porous soil, where the water is held superficially, and is then re-evaporated it amounts to 16, 17, and 18 inches. In extreme cases one way it will be as low as 11 or 12 inches, and in extreme cases the other way as high as 18. Upon hilly ground of the character of the watersheds which are used in Lancashire, Yorkshire, and Scotland, where mostly gravitation works are established, the evaporation may at the mean be taken to be 14 inches. At Sheffield we have ascertained it to be very nearly 15 inches, although the ground is very elevated, ascending to 1,500 or 1,600 feet high, but it lies rather with a southern aspect, and the ground is mossy and a good deal of water is held superficially, and of course is re-evaporated without running off or penetrating deep. There we have found that the evaporation is more nearly 15 inches than any other quantity. However, we usually take now for such ground about 14 inches. Then the final result after making those two reductions is the quantity which we hold can be dealt with, and which we know and have ascertained is capable of being dealt with.

7505. (*Chairman.*) Do you mean the waste which runs to the sea and the evaporation?—I mean to say that we first deduct one-sixth, and then the actual amount of evaporation taken off the rainfall leaves the quantity upon which a town may depend, providing the reservoir is made of the large size which is necessary even then to store that quantity.

7506. As to the quantity taken up by absorption by plants and grasses, and every other growing vegetable, that will ultimately find its way, will it not, to your reservoir?—Although it is received into the body of the plant it is given off again by the leaves, and it is taken into the evaporation.

7507. (*Mr. Harrison.*) You include evaporation and absorption generally, do you not?—There is absorption by vegetation but not absorption by the ground, because whatever is absorbed by the ground comes out again in springs, and of course contributes to the reservoir, and whatever that may be it comes out again as part of the water which is stored in the reservoir, and is not to be taken into account. It is an utter fallacy to take that into account separately; it is a part of the quantity of water which is received into the reservoir, which being stored in the reservoir comes in at one end and is given out at the other; and in the cases in which by error the springs have been dealt with as in addition to the reservoir capacity there has necessarily been a failure, because the effect of the reservoir is to store the whole, and if you were to separate the springs and bring them round and deal with them separately, all that you would want would be a larger reservoir which would be capable of adding so much more to those springs as to make up the same average—it makes no difference whatever. Therefore we never in any cases take into account the feed of the reservoir by the springs. Take the Leicester reservoir—there is always water running into it; nevertheless, inasmuch as there is always water going out of it, the final result of the working of the reservoir is that which is indicated upon the diagram.

7508. (*Chairman.*) If I understand you rightly, you first take one-sixth for waste which is now a well-established principle of constructing those reservoirs, and in point of fact, after deducting a sufficient quantity for evaporation, which will include all purposes of evaporation and absorption, you look upon the ground itself as the great reservoir, and what we are in the habit of calling reservoirs are simply mechanical conveniences for the purpose of catching and storing water?—The ground out of which the springs issue is a part of the reservoir.

7509. Do I rightly understand that, taking the metropolitan area for example, or taking the water-shed of the Thames, the evaporation of 12 inches would be a fair allowance?—No, the evaporation in the area of the Thames is 16 inches. There is very little hilly ground in the drainage area of the Thames, and the surface is not hard and the water does not run off.

7510. (*Mr. Harrison.*) You hold in your hand a diagram upon which you say the reservoirs are equal to 240 days supply; do you calculate that supply by the mean cubic contents of the reservoir itself, or do you make allowance for what would be flowing in in the intermediate time in springs?—No allowance whatever for the inflow; it is 240 days, and you require the inflow in addition.

7511. Taking that diagram, you appear there to have had eight months of continually diminishing level in your reservoir. During the whole of that eight months was there no supply either from rain or from springs into the reservoir?—A very considerable supply.

7512. Then the 240 days reservoir had become pretty nearly exhausted, had it not?—Yes, very nearly.

7513. That would almost go to show that in the eight months you would have nearly exhausted the whole of your supply without any supply at all from springs or anywhere else?—The reservoir would have been totally exhausted if there had not been some feed into it; it would have been exhausted a month earlier than the period at which the drought ceased.

7514. (*Chairman.*) In a reservoir of that capacity a foot at the bottom would not be at all equal to a foot at the top?—No, the capacities are as the cubes of the depths, and when we got down near to the bottom, as shown on the diagram, we had not a month's water.

7515. (*Colonel Harness.*) If it had been full it would have contained 240 days' supply, but the deficiency from fulness was more than what you had got from the springs?—Yes. The springs I suppose would give us the difference between the duration of the drought and the capacity of the reservoir. Taking it that the reservoir is empty, for the sake of observation, and that it took nine months to empty it, then, if the reservoir holds eight months storage, we got one month by springs.

7516. (*Sir B. Phillips.*) How long is it since this reservoir was made?—It was made, I think, in 1852.

7517. And you are speaking of 1865?—Yes.

7518. Between the years 1852 and 1865, at any one period, was the reservoir ever known to be as low as it was in 1864—that is to say, as nearly exhausted?—In the year 1864, and again in 1865, it was in the same condition, but antecedent to that it was not so and the reason for that was partly because there had not been the same amount of drought, but it was partly because the full supply had not been given. The company was a new one, and had not got the whole amount of its tenants.

7519. (*Chairman.*) The water line was depressed in 1864, and that accounted, did it not, for the deficiency in 1865?—Yes, that is always the case. A reservoir would be of no value if it was not constructed so as to guard against that contingency.

7520. (*Sir B. Phillips.*) Have you any idea of the nearest approach to the same state of things between 1852 and 1864?—No, I have not, because those diagrams were not kept from the first.

7521. (*Mr. Harrison.*) Have you the result in 1865 in the same reservoir?—Yes (*producing another diagram*). The difference between one and the other when you are at the bottom of the wine-glass, is a mere drop.

7522. (*Sir B. Phillips.*) What is the population of Leicester?—The population is 90,000, and the number supplied is 60,000.

7523. Have you any idea of the quantity supplied per diem to each person?—We supply somewhere

about 1,500,000 gallons per day, or a little under; that is about 24 or 25 gallons in summer (in winter it is less), including that supplied for manufacturing purposes.

7524. (*Mr. Harrison.*) It is singular how nearly the line of decrease is uniform throughout the greater part of the period, although you are getting towards the bottom of the glass?—Yes.

7525. It must have been either by limiting the quantity that they were using in the towns, or you must have had some additional rains?—Yes; rains had come in and helped towards the latter end of the year.

7526. (*Colonel Harness.*) I do not yet quite see why you take away the one-sixth before you take away the evaporation and absorption; because you might find, might you not, that you had got nothing left by adopting that process?—There are cases in which there actually would be nothing left, and those are the cases in the Fens of Lincolnshire, in which there have actually been years when they have had nothing left.

I made a reservoir in Lincolnshire, and the area from which the water is supplied is partly chalk, and very full of springs. The springs ceased to flow on the 1st of May, and they never ran again till the following Christmas Day; and the little flow from the springs at the commencement of the year was the produce of the rain of the preceding year. There are such cases, although they are not frequent. There is another thing which I should like to mention to the Commission, because it is very important. In consequence of these observations, which have now extended over many years, I have had occasion to collect a great number of rainfall tables, and amongst others I have got that of Greenwich for a period of 53 years, from the very commencement of reliable gauging down to the present time, and the mean of the whole is 25·36 inches; but in the year 1864 the rainfall was only 16·8 inches, whilst in the year 1824 the rainfall reached the mean quantity for this neighbourhood of 36·3 inches. With the permission of the Commission I will hand in the following table:—

TABLE of RAINFALL at the Royal Observatory, Greenwich.

Years.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total Fall in the Year.
	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.

T. Hawksley, Esq.

10 Dec. 1868.

This leads me simply to make an observation again upon the averages. If we were to deal with averages we should want to store that 36·3 inches which occurred 40 years previously, and to distribute it so as to come in aid, in point of fact, of the 16·8 inches. For reasons which I have given in part, you could not have stored, by any system of reservoirs which it would be possible to make, that 36·3 inches. I have not yet come to the rule, but we find that by the reservoirs of the great magnitude which I am going to mention, we can store and regulate (for that is the thing wanted) the rainfall of three consecutive dry years—not of the driest years, but of three consecutive dry years. And we find (and it is a very curious fact again, but it comes in justification of what I have already said) that the average rainfall of the three consecutive dry years, taken from any reliable table you please, containing a long series of rainfalls, is exactly one-sixth less than the average of the whole. I give you that as a general law, which within very narrow limits will be found to be true with respect to all rain tables of a reliable character.

7527. And that proves the waste, does it not?—It has nothing to do, for my present purpose, with the waste, but with the capability of storage.

7528. It is the means by which you arrive at the conclusion that one-sixth does pass off to water?—No, it only corroborates it. We arrive at that by actual gaugings upon waste valves and so on, but not in this way; this corroborates it, and I shall make important use of this observation hereafter. But I will, just at the present moment, interrupt myself to state to the Commission what has happened within the last two or three days. I have recently made a very large reservoir based upon the same principles of calculation for the town of Barnsley in Yorkshire, and the water is derived and stored exactly in the same way in which it has been proposed to derive and store water for the use of London. You know that the past summer has been very dry, and as a matter of course that reservoir sank down prodigiously, only a fraction of its full contents was left in the bottom. There have just now come floods. It is a very large reservoir, containing, perhaps, 350,000,000 gallons. That reservoir has been suddenly filled up, and the water continues to run and is now flowing down to the sea in large quantities, and is lost for ever for the supply of the town. There is a practical instance. It was only yesterday, and merely as a report of the fact from the clerk of the works, that I became aware of it. There is a weir there, I think, 60 or 70 feet long, and the water was going 7½ inches deep over that weir after having filled the reservoir in the short time in which it did fill it. That water is gone for ever. It would be quite impracticable to make reservoirs which would store that and all other floods which would be in excess of the ordinary rainfall. Now let me add to that that we shall probably have at all events the usual winter weather; we may have a great deal more wet weather than usual in order to balance the seasons, because they must be balanced some time. Between this period and probably next May that reservoir will be running over, large as it is, and the water will be going into the sea, and will be lost for use. That happens to all reservoirs, and unless the proper deduction be in the first instance made for that quantity which is inevitably lost, the waterworks must fail, and in consequence of that allowance not having been made waterworks have failed. Then I come now to mention to you the rules for the proportioning of the reservoirs, those rules which experience, and experience alone, has been the means of teaching us. We find this, that in wet districts not only does the rain come in greater abundance but it comes more frequently; and in consequence of its coming more frequently we require a less number of days storage to equalize the supply in the manner that I have mentioned, for the supply of a town, and it has been my endeavour over a long course of years to ascertain whether there was any approximate law which could be applied to the determination of the number of days storage requisite in the cases in which the rainfall was 80 inches, perhaps, on the one hand and in the cases in which it was not more than 20 or 22 inches on the other; such, for instance, as in the mountain districts of the north of England very adjacent to the Atlantic on the one hand, and in the flat low districts in the rest of England, the fen districts as an instance, on the other hand, where the rainfall is exceedingly low; and by means of a great number of facts collected over many years, and by pricking them off in a diagram upon a piece of paper, I have been enabled to draw a curve through the prick marks which have fallen up and down, a little above and a little below, and so on, but a curve which would as nearly as possible pass through them. By means of that curve I can find very nearly the number of days' storage which is requisite in different parts of the kingdom where the rainfalls are very different, and it is by that means that I know that in one part of the kingdom the number of days' storage may be, by possibility as low as 150, while in another part of the kingdom it will rise up even to as much as 300.

7529. (*Mr. Harrison.*) You gave us your calculation, did you not, in the particular case of the Welsh scheme, as 170 days?—I estimate that the produce in the case of the Welsh scheme will be, perhaps, about from 24 to 27 inches of rainfall, which would have to be divided, of course, in the usual proportions, that is to say, two-thirds for the service of the town and one-third for the compensation of the stream, those being the usual proportions, and that would give, of course, 16 inches for the service of the town off that watershed. That is the storable quantity; more would fall and then you must take off the quantity which could not be stored in wet years; and that brings me to the observation, that the quantity available for the town would, according to my estimate (but I wish not to have so important a subject merely dependent upon estimate) amount to about 130,000,000 gallons a day. I have no doubt that that is very near the practical result and upon that I wish to make one further important observation, and that is with regard to the small quantity of water which flows off these drainage grounds in dry years. It so happens that for 25 years I have been intimately connected in one way or another with the river Severn. I am concerned for parties in the navigation question. I made the waterworks at Worcester. I was engaged upon the waterworks at Cheltenham and some of the other neighbouring places and we have had to gauge the water actually flowing off. Questions arose which rendered it necessary to gauge the water. There is a weir at Tewkesbury through which the water of nearly 2,000,000 acres of drainage ground passes.

7530. (*Chairman.*) The only point which we are desirous of inquiring into to-day is your experience with regard to the year 1868?—This is an important part of it, because of course the feed into the reservoir is a part of the question of the defects of reservoirs in the year 1868 as well as in other years.

7531. The main point will be this, whether, having regard to the deficient rainfall of this year, the loss of water would be sufficient to cause you to re-examine your previous figures, whether the basis of your calculation may not be interfered with by this exceptional year, or whether there has been sufficient margin taken in all cases of calculation for the reservoir capacity to be equal to the short supply of this year?—By my method it would just cover the short supply of this year, but not by the ordinary method, and not by the method which I myself used in former cases and which was used at that period by all engineers.

7532. Taking credit for, and having regard to, the deductions which you have made from the actual rainfall, and the calculations as to the quantity in store, you believe that, if those calculations were strictly adhered to for this year 1868, the deficient fall of rain of this year 1868 would not interfere generally with your system?—No, it would, as nearly as I can make out, just balance, but not more.

7533. From that fact, that it is just balanced by his special care, would you be inclined to make a greater deduction or to increase your margin, supposing you were laying out new works to-morrow?—I would if I could obtain the money for that purpose. Of course I should always like to retain a reasonable quantity of water at the bottom of the reservoir, not merely as a sort of bank to draw upon to cover mistakes, but because the water which is drawn from the bottom of a reservoir is never in a satisfactory state, and therefore I should always wish to have a few weeks storage left in the reservoir under the worst circumstances, and of course the number of days in those few weeks ought to be added. But that is not all, it very much depends upon how the rainfall is ascertained If the rainfall is not ascertained by a fair distribution, I do not use the word "fair" in an improper sense), of the rain gauges over the whole area, very great mistakes would be made, because if rain gauges are placed in a gorge, or if they are placed on the lee-side of a hill, the quantity of water they will gather is enormous, and any average drawn from those rain gauges would be utterly fallacious. I can give you many remarkable instances, but I want to apply it now in another way, and what I particularly desire to state is this, that in the case of an important project like any for the supply of the metropolis, I am not speaking of a particular project, but anybody's project, it might be my own; but in any project for the supply of the metropolis by gravitation works, the only reasonable way of ascertaining the actual quantity is to put down weirs upon the largest streams, and to attach to those weirs a mechanical instrument of a very simple kind, which shall register upon a piece of paper the height of the water at all times, and the number of hours during which the water flows at that height. Then you can do this, you can not only calculate with perfect precision what water comes off the ground, which is really the only thing to be ascertained, but you can ascertain, by putting it upon a diagram, how much of that water you can store. Because all that you have to do is to make a table, you know the quantity that you will have to draw out, and you assume that you draw out so much a day, and then you put in the quantities which are indicated by that instrument. Then you will find, as completely as if the reservoir was made, how much will go to the sea, how much continues to come at the time the reservoir would be full, and instead of having any vague conclusions you will have a practical fact. If a thing of that kind were set about now, and continued for a considerable number of years, and it were done by the mechanism which I speak of there would be nothing to entertain any doubts about, you would get the facts. All that you would then have to consider would be what size of reservoir you would want to furnish the requisite quantity of water, and what works you would have to make to convey it to London, but at present everything is perfectly vague.

7534. (*Mr. Harrison.*) Has it not been your experience during this season that all the gravitation works have been short generally of their reservoir storage?—Nearly all of them; there are but two or three exceptions in the whole. Leicester is one, and that is because their reservoir is made of so large a comparative magnitude; and Barnsley is another which is made upon that principle.

7535. In the case of Newcastle, they pumped largely from the river, did they not?—Yes, very largely from the river, and for many months certainly they have got a much greater quantity of water from the river than they have got from the drainage area.

7536. As regards their reservoirs, are you aware that even up to last month they were nearly empty?—I have not been there; but having made the works at Sunderland, and having been very much down in the neighbourhood I have heard it and known it as a general statement, but I have not been up to the reservoir.

7537. Have you not seen a report which states that they have determined upon going six miles further off, and are making a very large additional reservoir in consequence of the drought of this year?—I am not aware of that. I have with me the Sheffield rain table, an important table, which I will put in.

The witness delivered in the following table:—

SHEFFIELD WATERWORKS.

RAINFALL AT REDMIRES.

TABLE showing the Three Consecutive Months in each Year which had the Maximum and Minimum fall of Rain.

1868	May - June - July -	*2·235				

* Six minimum. † Six maximum.

The minimum three consecutive years give a mean of only 33 inches = $\frac{1}{6}$ less than the general average.
The lowest year is $\frac{1}{5}$ below the general average.
The highest year is $\frac{1}{4}$ above the general average (usually $\frac{1}{3}$).
The ratio of the highest to the lowest is nearly 49·28 = 7·4, but more usually it is 2·1.
The loss by evaporation is at Sheffield fully 14 inches per annum, and by Mr. Gunson's returns is nearly 15 inches per annum.

The witness withdrew.

Adjourned.

ERRATUM.

The following is to be substituted for the corresponding paragraph in Art. 194 of the Report, which contains an accidental error:—

It appears that the sources most free from probable contamination, such as the springs forming the head waters of the Thames, show in 100,000 parts of water, 3,260 parts of "previous sewage contamination," whereas the Thames just below Lechlade contains only 1,270, and after experiencing various fluctuations as it flows by Oxford, Reading, and Windsor, still shows at Hampton only 1,640, or only one-half of that in the head springs of the river. The Kennet above Hungerford contains 830, while just above Reading the quantity is 0. The chalk springs at Amwell give 3,740, while the East London Company's water at London shows 1,077. The water in the Wandle at Mitcham shows less than in the Croydon well.

APPENDIX.

APPENDIX A.

REPORT on the SELECTION of SAMPLES of WATER in the CUMBERLAND and WESTMORLAND LAKE DISTRICTS.—By WILLIAM POLE, F.R.S., Mem. Inst. C.E. (*This Report is illustrated by the Map, Appendix F.* 1.)

SIR, Westminster, May 29, 1867.

1. I BEG leave to report, that in obedience to the instructions of the Commission, I have visited the lake district of Cumberland and Westmorland, proposed by Messrs. Hemans and Hassard as a source of water supply for London and other large towns.

2. My instructions were, to go over the ground and select points where samples might be taken so as to give a fair idea of the waters of the district; to take such samples and forward them to Dr. Frankland; and to note during the selection any observations that might appear worthy the attention of the Commission.

3. I was furnished with the pamphlet, "On the future Water Supply of London," published by Messrs. Hemans and Hassard, in which their scheme is stated; and I was also favoured with copies of the evidence given by these gentlemen before the Commission.

4. I had a long consultation with Dr. Frankland, and made myself fully acquainted with his views and wishes as to the general mode of selection of the samples; the quantities required; the mode of taking and preserving them; the precautions to be adopted, and so on; all which I have endeavoured to carry out with every possible care.

5. I also had an interview with Mr. Hassard, who gave me useful preliminary information respecting the district, and further explained the views of Mr. Hemans and himself in reference to the water collection.

6. I received information of the sanction of Her Majesty's Treasury to my engagement on the 11th April, and immediately put in hand the necessary preparations for the journey; but the glass carboys to contain the water had to be made specially in Yorkshire, and I could not get them delivered into the district till the 10th May. I have found the collection take more time than I anticipated, from the distances which many of the points lie from places of convenient access, and from the difficulty of transport to and fro.

7. In considering the quality of the water likely to be afforded by any particular gathering ground, it is necessary to notice not only the mineralogical composition of the rocks, but also the nature of the surface of the ground, as regards conformation, covering, and any accidental circumstances that might affect the purity.

8. The rocks in the greater part of this district are such as are usually considered most favourable for preserving the purity of the water falling on them, being practically insoluble, and very little liable to disintegration. I shall note hereafter the places where exceptions to this occur.

9. The conformation of the land is very favourable; the hills rise to a great height, and their slopes are generally steep and rugged, so that the water runs quickly off. This is not only conducive to the purity of the water, from the less time it has to take up foreign matters, but it also tends to diminish the quantity exposed to absorption and evaporation, and so to increase the proportion of rainfall available for storage.

In the upper parts of the ground there is a good deal of bare rock, but the greater part is covered with grass, used for sheep pasture, and sprinkled over here and there with furze bushes.

10. A question has been raised as to the existence of peat moss in various parts of the district. To have investigated this subject specially would have required much longer time and greater expense than I was authorized to devote to my work; and I can therefore only note such facts and impressions as presented themselves during the collection of the samples. I have reason to think that a good deal of moss may exist on the flat places about the hills, and on some of the lower commons and more slightly inclined lands. Names frequently occur on the maps which lead to this inference; for example, there are two "Mosedales," and other names occur in which moss is specially mentioned.

Probably the best test of the existence of moss is the brown colour of the streams in rainy weather. As nearly all my samples were taken in fine weather, they led to no conclusion on the subject; but I found the inhabitants allude frequently to the brown colour of the streams during rain.

The single day's experience I had of somewhat heavy rain, although lasting only a few hours (see notes on samples *B c* and *B d*), confirmed this information, and showed how desirable it will be for the complete investigation of the subject that samples of the water should be taken under different natural conditions.

It has been stated, on good authority, that brown water running from moss becomes blanched by storage in lakes or large reservoirs; and this district might afford an excellent illustration of the fact, if confirmed by careful future observations.

11. Generally speaking, but little of the area proposed to be used for water collection under this scheme is tilled land, or is much inhabited. I shall notice elsewhere the exceptional localities.

In some parts of the district mining operations are carried on, and these deserve serious consideration; I shall mention them fully in the proper places.

I am not aware of the existence of any manufactories within the proposed area, or of any other circumstances calculated to deteriorate the quality of the water.

12. In fixing on appropriate points for the selection of the samples, it has been necessary to have reference to the somewhat complicated arrangement of the several distinct drainage grounds comprised in Messrs. Hemans and Hassard's scheme. This arrangement, I understand, to be as follows:—

To the north of the great dividing range of hills running east and west between Scaw and Shap fells, lie the three lakes, Thirlmere, Ullswater, and Haweswater. They are all at considerable heights above the sea, but the first and third are much above the level of the centre and largest one, Ullswater.

It is proposed to raise still further the levels of these two higher lakes, by damming up their outlets; and also to increase the quantity of water running into them, by adding the drainage from the sides of neighbouring hills, to be collected and brought into the lakes by intercepting conduits at proper levels.

The waters from these two lakes will then be conducted by large conduits into the centre or lower lake, Ullswater, which will be treated as a great distributing reservoir from which the supply will be drawn off as required. This lake has a large drainage of its own, and it is intended to increase it by a small additional district in the same way as the others.

The natural outlet of the Ullswater lake is at the north end, by the river Eamont, flowing into the Eden, and so by Carlisle into the sea. It is proposed, however, in connexion with the present scheme, to tap the lake also at its southern end, and to run water off from it by a tunnel to be formed under Kirkstone pass, and a conduit carried round the slopes of the hills above Windermere, and so away southward.

Provision is also made for intercepting, at a future time, if necessary, further drainage on the south side of the great dividing range, and adding it to the eduction conduit on its way.

13. Having this arrangement in view, I have classified the samples of water as follows, according to the various divisions of the collecting area:—

A. Thirlmere proper.
B. Drainage to be added to Thirlmere.
C. Haweswater proper.
D. Drainage to be added to Haweswater.
E. Drainage of the Lower Lowther.
F. Ullswater proper.
G. Drainage to be added to Ullswater.
H. Additional drainage to be collected, if necessary, on the southern slopes of the main dividing range of hills.

14. At the desire of Dr. Frankland the more important samples have been taken in quantities of eight gallons each, the subordinate or less important ones in quantities of two gallons.

A list of the samples is appended to this report, and the places where they were taken are indicated approximately by red circles on the accompanying small map. But in case it should be important to know the localities more exactly, I have taken care to register the exact points on a copy of the large ordnance map (scale six inches to a mile) which I had with me.

15. It may be desirable I should state the precautions adopted in regard to the samples.

They were collected in glass carboys, holding two gallons each, encased in wickerwork, and provided with well ground glass stoppers. These vessels were all perfectly new, and made expressly for the purpose by the Aire and Calder Glass Bottle Company.

In taking the water, each bottle was cleaned round the neck and stopper, next rinsed three times with the water it was to contain (never less than a quart) and then filled to within a short distance of the stopper. This was fastened down with leather and sealed, and the leather covered with canvas, a record being kept of the number of the bottle, the exact locality, and the attendant circumstances.

From the lakes, where possible, the water was taken by going off in a boat to deep water, and immersing the bottles below the surface. In the streams, places were chosen as free as possible from any risk of accidental impurity, and the water was ladled from the running stream with a ladle of ebonite or "hard india rubber" (a material recommended by Dr. Frankland) attached to a long handle, and was poured into the bottle through a funnel of the same material.

16. I have appended to this report a brief journal of the weather. It will show that, with the exception of one day, all the samples were taken during fine weather, and I think they may fairly represent the fine weather drainage of the district.

17. I made a very rough attempt to estimate the quantity delivered by each stream at the time of my taking it, but I did not attach much importance to this, knowing how very fallacious isolated gaugings would be in such a country, even if much more accurately taken than I had the opportunity of doing.

The smaller streams were running from 1 or 2 to 5 millions of gallons per day, and the general discharge appeared to be from half a million to one million gallons per day for each square mile, or say about $\frac{1}{20}$ of an inch depth per day.

18. I will now proceed to describe in detail the circumstances under which the various samples were taken.

A.

Thirlmere proper.

19. The district naturally draining into this lake has an area of about 13 square miles.

20. The whole of the district is composed of low members of the Cambrian system, called by Mr. Ruthven, "Green slates," having occasional dykes of porphyry and other igneous rocks, and containing some mineral veins.

The surface is very steep and rugged, formed either of bare rock or grass, and is almost uninhabited. It appears to be naturally of the most favourable character for the collection of pure water.

21. It is proposed to raise the level of the lake 64 feet. I see no difficulty in this measure; the outlet being a narrow gorge which could be easily dammed up. A good deal of land would be covered and some few buildings would be destroyed, but the compensation for these would probably not be very heavy. The road also under Helvellyn (leading from Keswick to Grasmere, and much frequented) must be raised where it descends near the lake level, but this would not be very expensive, and the road itself would be improved by the change.

22. I have considered it sufficient to take two samples of the water of this district, one from the lake itself, and the other from the principal stream running into it.

Sample A a. Thirlmere.

23. This sample is of eight gallons, contained in four bottles, Nos. 12, 55, 59, and 60, and was taken on the 13th May.

I should have preferred taking the water from the middle of the lake, but there are no public boats upon it, and the use of the private one, belonging to Mr. Lees, was refused me.

I therefore took the water out of the strong current flowing under the wood bridges between the two portions of the lake, and have no doubt it will fairly represent the general contents.

24. The water was beautifully transparent and colourless, and the small submerged pebbles were quite clear and free from vegetation, which is, I believe, generally considered a sign of freedom from mossy contents in the water. The temperature was 12° Cent.

Sample A b. Main feeder to Thirlmere.

25. This is a two-gallon specimen, bottle No. 40, taken on the 13th May. Snow had fallen on the high hills the evening before.

26. It was taken from the main feeder running into the south end of the lake (consisting of the Wythburn beck combined with the gill from Harrop tarn and others) at a point below the junction of the streams, and about 600 yards above the lake.

27. The water was very clear and colourless. Temperature about 11° Cent.

Leadworks in Thirlmere District.

28. Mr. Hassard has mentioned leadworks in this district, and I thought it right to look at them. They are situated on the steep slope of Helvellyn, forming the east side of the drainage ground.

Levels are driven, at several different places, into the rock, and the mineral is brought down to a point a few hundreds of feet above the lake, where the crushing and washing processes are performed.

The mineral consists, I believe, of the usual "galena," combined with a matrix of quartz and slaty rock, and calcareous and barytic spar. The preparation consists first of crushing the mineral between rollers, and then sorting it by various contrivances in which gravity is the agent, so that the heaviest portions, forming the lead ore, are separated from the lighter or earthy ones.

The material is constantly washed during the process, and the water which runs away carries with it a great quantity of solid matter, and is much fouled.

29. I brought away a two-gallon sample (*A c.* bottle No. 47) of this water, taken on the 13th May, from a point in the stream a few yards before entering the lake.

30. These lead works are already large, and they are increasing in importance; the levels in the hill are extending, and additions are being made to the machinery. They therefore deserve consideration, as affecting the water supply, and I shall make further remarks on the subject in speaking of the Ullswater district.

B.

Additional Drainage to be artificially conducted to Thirlmere.

31. The area draining naturally into Thirlmere being but small, it is proposed to increase it by artificially conducting to the lake the drainage of certain other adjoining districts, viz.:—

1. A portion to the west and north-west of Thirlmere, containing about five square miles.
2. A portion to the north-east, containing about 21 square miles.
3. A portion on the south above Grasmere, about six square miles.

B 1. Western and North-western Addition to Thirlmere.

32. The hills separating Thirlmere from Derwentwater and Borrowdale are said to receive a very large rainfall, and it is proposed to utilize some portions of the western slopes, to the extent of about five square miles, by diverting their waters into Thirlmere.

A portion of the drainage from the western side of Cold Barrow fell, including the little mountain lake called Blea tarn, is passed by a short tunnel through the ridge, direct into Thirlmere. A catchwater drain is then run along the hill side above Derwentwater, and passing round Bleaberry fell is turned downwards to the east and introduced into the north end of Thirlmere. This intercepting conduit also collects in its way the waters of a considerable stream called Naddle beck, which at present runs northwards in a valley of its own, and enters the Greta a little below St. John's beck.

33. The whole of the district thus appropriated is excellent gathering ground; its geological formation is the same as described for Thirlmere, and its surface is entirely rugged steep rock, either bare or covered with spare grass.

The following two samples will, I believe, fairly represent its waters:—

Sample B a. Watendlath tarn.

34. The water that runs through this mountain tarn is supplied from the upper part of Cold Barrow fell, and affords a good example of the drainage of the high western slopes of the hills separating Thirlmere from Borrowdale.

The sample, two gallons, bottle No. 51, was taken 14th May, from the outlet of the tarn above the little village. The water was clear and colourless, but there was a little tendency to vegetation on the pebbles. Temperature, 12½° Cent.

Sample B b. Naddle beck.

35. This stream gives a good example of the drainage running from the north-western parts of this district.

The sample, two gallons, bottle No. 53, was taken on the morning of the 13th May. Snow had fallen on the high hills the night previous. Temperature of stream 8° Cent.

The place was about 130 yards above the crossing of the road from Keswick to Grasmere.

The water was quite clear and colourless.

B 2. North-Eastern Addition to Thirlmere.

36. This addition is proposed to be effected by forming an intercepting culvert to catch the Barrow beck, the Trout beck, the Mosedale beck, and the general lateral drainage falling into the south side of the river Glendermackin; and also the Helvellyn gill, running into the St. John's stream, a little below the outlet of the lake. These various streams are to be led southwards, by the intercepting culvert before mentioned, and to be turned into Thirlmere, at a proper altitude to correspond with its raised level.

37. This is an extensive district, being about 21 square miles; its geological structure is the same as Thirlmere, but it has considerable variety in its superficial character. I have selected three streams for samples, viz., Trout beck, Mosedale beck, and Helvellyn gill.

Samples B c. Trout beck (Greta).

38. There are two streams in the lake district, both having the name "Trout beck," one falling into the Greta, the other into Windermere.

The Greta Trout beck drains at its higher portion the steep and rugged sides of the Great Dodd, the Wolf's Crags, &c.; but it also collects, at a lower level, the water from the flatter slopes of Matterdale common, comprising, I believe, much peat moss. I had no occasion to go over this district, but I was told that portions of it were being drained and cultivated, and the existence of a manufactory of drain tiles at Trout beck station gives some support to the information.

I have two samples from this beck, one taken on the 11th of May (rainy), the other on the 15th (fine and cold).

39. The latter, a two-gallon sample, bottle No. 49, represents, I should think, about the ordinary fine weather condition of the brook; it was taken at the bend above the ford, near the railway station.

The stream was transparent, but very slightly tinged with brown, and had a little white scum here and there; the sunk pebbles had a good deal of vegetation on them. Temperature 7½°.

40. The other sample, two gallons, bottle No. 57, was taken at the bend near Moor end, and about half a mile above the junction with the Glendermackin. This is a mile lower down than the other sample, but there is no accession of water or change of any importance in the interval.

41. This sample was, however, obtained under very different circumstances, shortly after some heavy showers. The beck was changed from a quiet brook to a large rapid river, and the water instead of being clear and colourless, had become turbid and dirty, and of a deep brown colour, with much frothy scum.

Sample B d. Mosedale beck.

42. This is also a two-gallon sample, No. 58, taken about 20 or 30 yards above the railway viaduct, on the 11th May, under the same circumstances as the flood sample of the Trout beck.

43. The drainage ground of this is very similar to that of the Trout beck last described, and the stream was in a similar condition, being much swollen, and delivering nearly the same quantity.

The water was as brown, but I think rather less turbid.

The river Greta was much enlarged and coloured at Keswick the day these two flood samples were taken, but in a few days it had subsided to its ordinary fine weather condition.

44. The two last samples give some idea of the great variations which take place in the character of the drainage of the district under changes of weather. But this idea is only very limited and partial, for the changes here recorded were only the result of a single morning's heavy showers, and cannot approach what must take place under a steady continuance of the heavy rain that this district is celebrated for. It was evident by the appearance of the stream channels that they were often subject to very much larger increase than took place under this temporary flush.

45. It would not be right to draw from the isolated flood samples any inferences as to the suitability of the water for being utilized in the proposed scheme, but if it should be found by further investigation that the moss or the cultivation, or both, render these streams unsuitable, it would not be difficult to separate the waters of the upper or rocky district from those of the common, turning the former into Thirlmere, and making use of the latter for compensation, impounding them in the compensation reservoir proposed to be made in St. John's valley. If the loss of this drainage ground to the general scheme was considered of importance, it would be possible, I should think, to add other gathering ground of a more unexceptionable character on the slopes of the Skiddaw group of mountains to the north of the Greta and the Glendermackin.

46. Other important inferences result from this comparison as affecting the artificial intercepting conduits proposed to be made for collecting the drainage of outlying districts, and conveying it to the storage grounds. If these conduits are to be effective in collecting all the available water, they must be of most ample carrying capacity, and most substantially constructed. And as, independently of this, the ground over which they have to pass is often very rugged and irregular, their cost must necessarily form a large item in the estimate of expenditure.

Sample B e. Helvellyn or How gill.

47. This is an important stream which runs down from the west side of Helvellyn, and would appear at first sight to belong naturally to the drainage of Thirlmere, but it is cut off from the lake by a low longitudinal ridge, and runs, united with other streams, northwards in a little valley of its own, uniting with the St. John's beck about half a mile below its issue from the lake. It is proposed to intercept this and other neighbouring streams, and to turn them into Thirlmere.

48. The gathering ground for this stream is unexceptionable, being almost entirely the steep slopes of Helvellyn.

49. The sample, two gallons, bottle No. 46, was taken 13th May, at a point just above the crossing of the main road.

The water was very transparent and colourless. Temperature 8°.

B 3. Southern Addition to Thirlmere.

50. It is further proposed to add to Thirlmere certain waters falling on the upper portions of the slopes to the south of the ridge dividing Cumberland from Westmoreland, and which now drain into Grasmere.

For this purpose it is proposed to form a conduit, which will intercept at the proper level the river Rothay, and the Easedale beck and other streams running into it, and to convey the combined waters through a tunnel formed under Dunmail Raise northwards into Thirlmere.

51. This will add about six square miles of land, receiving, I believe, a large quantity of rain. The geological and physical features of the ground are the same as described for Thirlmere, and the water is therefore likely to be of the same quality.

Sample B f. Upper Rothay.

52. The sample, eight gallons, bottles Nos. 14, 16, 19, and 33, was taken, 22nd May, from the river Rothay, above the village of Grasmere, and a little below the junction of the Easedale beck.

The stream was clear and colourless, with vegetation on the pebbles. Temperature 11½°.

C.

Haweswater proper.

53. The area at present naturally draining into Haweswater is about 12 square miles.

54. The geological formation is the same as described for Thirlmere, viz., entirely "green slates and porphyry."

55. The physical features of the ground are also very similar, namely, steep and rugged slopes. The surface consists generally either of bare rock or grass, but the eastern slope of the lake is covered with trees.

56. It is proposed to raise the level of the lake 42 feet by a dam at the outlet. This will be quite feasible, as the valley is narrow at that place. It will involve some expense for land and buildings, and for diversion of the road, &c., all which, no doubt, has been taken into account.

57. I have taken two samples of the water of this district; one from the lake itself, and the other from one of its principal feeders.

Sample C a. Haweswater.

58. This is eight gallons, contained in four bottles, Nos. 34, 43, 44, and 50.

It was taken on the 16th May from the lake itself, about 50 yards off the Earl of Lonsdale's boathouse, one of his lordship's boats being courteously placed at my disposal by his steward. Temperature 12°.

Sample C b. Measand beck.

59. This is one of the principal tributaries to Haweswater. It runs from a steep lateral valley, and forms in its lower portion almost a constant succession of waterfalls.

The sample, two gallons, bottle No. 52, was taken on the 16th May at a point immediately above Measand Hall.

The water was clear and colourless, but some persons standing by said, "It came from moss, and that there was better water elsewhere which came over fells."

D.

Drainage to be artificially added to Haweswater.

60. It is proposed to make two intercepting conduits to collect the waters of several portions of land now draining directly into the Lowther, and to turn them into Haweswater.

The conduit to the north will take Heltondale beck, Gill beck, Hews beck, and several smaller ones.

That to the south will begin with the High Lowther at Coopers Green, and will also take the large stream in Swindale and the Naddle beck close adjoining the lake.

61. It is proposed to relieve a part of this latter conduit by forming an auxiliary reservoir in Swindale, as shown on the map.

62. These operations will add about 26 miles to the area draining into the lake.

The ground, as far as I could see it, appears to be of the same character as that round the lake, and I should think the water would be of equally good quality.

I have only thought it necessary to take one sample.

Sample D. Upper Lowther.

63. Two gallons, bottle No. 37. It was taken on the afternoon of 16th May, from a point about 50 yards above Rossgill bridge, and a little below the junction of the Swindale stream with the Lowther. This point is about a mile below where the Swindale beck is proposed to be taken, and about three miles below the place where the conduit is to intercept the Lowther. It may therefore probably be a little less pure. The water was clear and white; but there was much vegetation on the pebbles. Temperature 15°.

E.

Drainage of the Lower Lowther.

64. Independently of the Upper Lowther and its high tributaries, described in the two foregoing sections, it is also proposed to make use of a drainage area of about 22 square miles on the lower part of the same river, extending from the intercepting conduits before named, down to a point about 1½ miles below Askham.

65. This tract of country is of quite a different character, in many points of view, from those previously described.

The greater portion of it is on the mountain limestone formation; the character of the surface is generally flatter, and, lying at a lower level, it is more cultivated and fertile, and more populous, containing many villages. It is plentifully interspersed with trees, Lowther park being entirely comprehended within this area.

66. This appears to me to be a less favourable district for water-bearing than the higher grounds C and D. The water would be likely to be harder, flowing over the limestone, and the drainage from the cultivated lands would give it greater organic impurity.

67. According, however, to the scheme proposed, as I understand it, this drainage becomes inseparably mixed up with those of the higher grounds. It is proposed to allow the water from Haweswater to run down its present course, namely, into the Lowther, and to tap this river at a point below Askham, and convey a portion of its waters by an artificial conduit into the north end of Ullswater.

68. I am aware that Mr. Hassard proposes, on account of the probable inferior quality of this water, to make arrangements for devoting it chiefly to compensation; but it appears to me that if the water in the upper Haweswater district is as good as I believe it to be, it would be a pity not to make use of it as a permanent addition to the general supply, and I think means might be contrived to do this. Possibly a small tunnel (four miles long) direct from Haweswater into Ullswater would not cost much more than the larger conduit (five miles long with one mile in tunnel) proposed to be made from the Lowther to Pooley Bridge, and it would certainly better repay its expense. This Lower Lowther district might then be left to its natural drainage; but the river would be regulated and its floods stopped; and if compensation was wanted in dry seasons, it could be afforded from Haweswater or Swindale.

69. It is not possible to get any satisfactory samples from this drainage separately; all I could do was to take one at or near the point below Askham, where it is proposed to tap the Lowther, this sample therefore representing the whole present drainage of the district above.

Sample E. Lower Lowther.

70. The sample was eight gallons, bottles Nos. 13, 29, 39, 41. It was taken, 15th May, from a point close to Low Gurdon bridge, in Lowther park.

The stream was 60 feet wide by about 18 inches deep, running about 45 to 50 millions of gallons per day. The water was clear and colourless, with a good deal of vegetation on the pebbles. Temperature 10°.

F.

Ullswater proper.

71. The natural drainage area of Ullswater is about 60 square miles. It lies in the "green slate and porphyry" formation, with the exception of a small part at the north-western end of the lake, which consists of the coarse conglomerates of the old red sandstone.

72. The surface is remarkably favourable for gathering ground. The lake is surrounded by mountains rising to between 2,000 and 3,000 feet above its surface, and whose steep slopes are either bare rock or covered with grass, with here and there patches of moss or bunches of furze. On the immediate edges of the lake are many plantations and ornamental grounds.

73. It is proposed to raise the lake five feet, but it would be impossible to tell the influence of this on the property and lands on the banks, without a minutely detailed survey.

74. I have taken samples of water from the lake itself, and from several of its tributary streams.

Sample F a. Ullswater.

75. This is eight gallons, bottles Nos. 1, 3, 4, 5. It was taken on the 21st of May, by means of a boat, from the lake itself near Pooley Bridge. The water was very clear, and its temperature about 9½° Cent.

76. The lake was said to be rather low. I endeavoured to estimate the quantity of water running out at Pooley Bridge, and made it between 35 and 40 millions of gallons per day; but the high wind blowing on the stream rendered the determination of the velocity very difficult and uncertain.

Sample F b. Airy beck.

77. This is one of the largest tributaries to the lake, running in about the middle of the western side. The sample, two gallons, bottle No. 56, was taken on the 17th May, a little above the crossing of the road. There was a little partial and light rain, and I believe the brook was running rather full. The water was clear, but with a slight tinge of brown.

78. *F e.* and *F f.* are other samples of feeders to Ullswater, which will be mentioned hereafter.

There are some large tributaries running into the east side from Martindale, but as the drainage ground of these is so obviously of the same character as the others, I did not think it necessary to take further samples. It is proposed to make auxiliary reservoirs in two of these valleys, which I have no doubt may be easily done.

Lead Workings in the Ullswater District.

79. I have mentioned lead workings in the Thirlmere district, but they assume much greater importance here.

On the east slope of Helvellyn, a little way up the Glenridding valley, lie the well known Greenside lead mines and works. They have been established and successfully worked for, I believe, 40 or 50 years; and the workings into the hill are very numerous and extensive. The lead ore is not merely separated and prepared (as at Thirlmere) but it is also smelted, and the produce sent away to Penrith in the shape of pig lead, the coal for the smelting

ing brought by the return carts. Some of the ore con-
ns silver, and this is also separated and smelted on the
emises.

80. The magnitude of the workings may be deduced
›m the information given me, that from 25 to 30 tons of
g lead are sent away weekly.

81. The crushing and washing processes for separating
e galena from its earthy matrix are the same as
scribed at Thirlmere, but on a much larger scale. There
e two different sets of works for the purpose, in different
rts of the valley, and the refuse is turned into the Glen-
lding beck and carried down into the south end of the
ke, forming large deposits, and discolouring the water for
great distance around.

I have brought away samples of the water.

Sample F c.—Glenridding beck.

82. This sample, two gallons, bottle No. 36, was taken
the 18th May from the Glenridding beck, about 100
rds below the crossing of the main road.

The stream was opaque white, like milk and water.

Sample F d.—Stream from Leadworks.

83. This sample, two gallons, bottle No. 42, was taken
e same day from the little stream running directly from
e leadwashing works, and, therefore, is much less diluted.
ıe actual working had stopped about an hour, or an
ur and a half, before I got to the place; but the water
›peared to be retaining its usual qualities.

Sample of the Deposit.

84. I also brought away a small sample of the earthy
›posit left by the water in the Glenridding beck, but this
›posit varied much in appearance at different places, and
doubt whether its nature may be correctly deduced from
ıe sample only.

85. There are other lead mines in adjacent valleys. It
›pears that levels have been opened in this district for
ad and other metals at various times for a long period,
ıd the traces of them are still seen in various places. It
ill only, however, be necessary to mention those that
›pear to be of importance at the present time.

86. I am told that a mile or two up the Grisedale valley,
›ening out close to Patterdale, there are mines which have
›en worked and given up again several times, the last
orkings having been very lately; and it is expected they
ıay again be resorted to. Nothing was doing when I was
ıere, and, therefore, I did not visit the site, but I have
rought away a sample of the water in the stream.

Sample F e.—Grisedale.

87. This is two gallons, bottle No. 35, taken 18th May,
little above Patterdale Hall. Water transparent and
olourless. Temperature 14½°.

88. In the Hayeswater valley, a little above the village of
ow Hartsop, there have been several workings at different
imes, old levels having been abandoned and new ones tried.

A pit is now being sunk at the junction of the Pasture
›eck, and worked with a horse gin. I am told that both
opper and lead ore are being found there, but there is no
vashing, nor any operation to pollute the water.

89. In the Upper Hartsop valley, however, about a quarter
f a mile above Hartsop Hall, there is a working of more im-
›ortance, as the mineral is crushed and washed by modern
nachinery on the spot, in the same manner as on Thirl-
nere, but on a less extensive scale. I am told that the
nines are ancient ones, resumed with success during the
ast few years. The ore is said to be rich in silver, but not
›lentiful, only about two tons per week being produced.

The machinery had been standing some days when I
visited the works, and therefore I did not take a sample
of the water; but the stream running from the washing
pits was still turbid and milky, and it was evident that
when at work it would send down much detritus.

90. The water from the mine runs by the Hartsop and
the Kirkstone becks into the south end of the little lake
called Brothers Water, where the sediment is deposited.

The stream running out of the north end of the lake is
quite clear and colourless; and after being joined by one
or two other rivulets, it becomes what is called Goldrill
beck, running through the village of Patterdale into the
south end of Ullswater. I have taken a sample from this
stream.

Sample F f.—Goldrill beck.

91. Two gallons, bottle No. 38, taken 18th May, ust
above Patterdale.

92. I am told that iron and copper ore are found in the
neighbourhood, but not at present in sufficient quantities
to pay for the working.

93. I have made inquiries whether any evil effects are at present produced on animal life by the water from these various works, but the facts are difficult to get at. It was said that in Ullswater, the char, and the fish called fresh water herrings, had disappeared or diminished, but that, both here and in Brothers Water, the trout were still plentiful and healthy, even near the mouths of the streams from the mines.

On the other hand, an intelligent farmer, the tenant of Hartsop Hall, told me he had frequently seen trout lying dead in the mine stream passing through his grounds, and that, in dry weather, when it was not much diluted, some of his live stock had suffered seriously from drinking it. It had been arranged he said, that it should be diverted, but this had not yet been done, as the workings were still experimental.

94. But apart from any noxious effects on health, it seems to me that the matter, whatever it be, at present brought down so plentifully from these works is likely to cause much trouble.

95. If the water is taken away from the south end of Ullswater, as soon as a current is established towards the discharge orifice, the matter held in suspension near the mouth of the Glenridding beck will inevitably find its way in that direction, and so the advantage of the lake as a settling reservoir will be lost.

96. But there is another evil which appears to me to deserve consideration on public grounds, independently of any water scheme. I mean the prospect of the more rapid silting up of the lakes where this detritus is deposited. We know that, geologically speaking, the lakes must, sooner or later, become filled up by the ordinary streams flowing into them, and the deposits round these are already very marked, particularly at the Patterdale end of Ullswater, where the flat meadows are evidently formed by deposited matter.

But under the natural course of things, this result would be protracted to a period that need cause no immediate alarm; whereas the artificial addition of detritus on such a large scale as is produced by these lead works will bring the effect to a much more proximate time. The mineral extracted from the mines, in order to get 25 to 30 tons of metallic lead, must amount to probably 600 or 700 tons weekly; and, though doubtless much of this is deposited on the hills, yet, if great care is not used, an enormous quantity will be sent down the stream, as the easiest way of getting rid of it. And this is shown in a practical way by what has already taken place, for the Glenridding stream has in these few years formed a delta at its mouth extending 100 to 150 yards out into the lake, and larger in extent than other similar streams have produced in a long course of time.

The effect in Brothers Water produced by the High Hartsop mines is still more striking. There a new cut has been made for the stream to enter the lake, and round the mouth of this stream, during the two or three years these comparatively insignificant mines have been at work, there has been formed a white delta tongue, 30 or 40 yards long, and 10 or 20 yards wide.

If these mines should go on, Brothers Water must in a great measure be destroyed; and in regard to Ullswater, which is of more importance, I believe that the south end of the lake must be very shallow, and that its silting up must progress rapidly.

97. Hitherto the three workings I have mentioned, namely, Glenridding, Thirlmere, and Harsrop, have been the only ones worked to any extent; but a general idea seems to exist of the possibility of other large veins being found; and, of course, if other important workings should be established in the district, or if the present ones should be materially extended, the difficulties arising from them would be magnified in a corresponding degree.

98. It has been proposed to divert the fouled drainage from the Glenridding works, to conduct it by conduits or pipes along the margin of the lake, and to deliver it into the river Eamont below the outlet. But under the present mode of working, I fear such conduits would be difficult to keep clear from stoppage by the deposit; and I should think the nuisance caused by delivering such a mass of detritus (which is at present arrested by the lakes) into the rivers and estuaries below would be strongly objected to.

99. I shall make some general remarks on the subject of lead workings in my report on the selection of samples in the Welsh district, where also they are carried on extensively; but I may say here that I am convinced it would be possible, by the extended use of subsiding tanks, and by great care in arresting and stacking the earthy matter on the hills, to reduce the water flowing away to such a state as would be either innocuous or capable of easy diversion; and I believe, therefore, that the existence of these leadworks need not necessarily form any bar to the use of the district for water supply.

G.

Addition to Ullswater Drainage.

100. It is proposed to add to the natural drainage of Ullswater, the gathering ground of about 13 square miles, drained by the *Dacre beck*, which falls into the Eamont about 1¾ miles below Pooley Bridge. It is proposed to tap this stream a little below the village of Dacre, and to convey its waters by a conduit to the north end of Ullswater.

101. The drainage ground of this beck is of a different character to that of the chief districts; it is over the old red sandstone and the carboniferous limestone; the lower part of the ground is comparatively low and flat, and is much cultivated. I should doubt whether the quality of this water will be equal to that from the other districts.

102. The *sample G.*, two gallons, bottle No. 45, was taken on the 20th May from a point immediately below Dacre bridge. The stream runs over limestone rocks covered with vegetation. The water was clear and colourless. Temperature 15°.

H.

Additional Drainage on the Southern Slopes of the Main Range of Hills.

103. In case the demand for water should become greater than can be supplied by the portions heretofore named, Messrs. Hemans and Hassard propose a measure for obtaining additional catchment area, to the extent of 53 square miles, from the southern slopes of the great east and west range of mountains before mentioned.

This area is coloured red on their map; and it will be seen that it is proposed to form a series of intercepting conduits, along the sides of the hills, from Rydal on the west to Borrow beck on the east, and so to catch a large portion of the waters which now find their way from these slopes into Windermere, the river Kent, or the river Lune.

104. This area being unprovided with any natural lakes at sufficient altitudes, it is proposed to form four artificial reservoirs, in the valleys of the Trout beck, the Kent, the Sprint, and Bannisdale beck, in which the waters would be stored, and from which they would be allowed to run off, either into the main conduit, for conveyance to a distance, or into their natural courses for compensation as might be desirable.

I have looked at the sites proposed in the two first-named valleys, and they seem favourable, regard being always had to the payment of compensation for injury done to lands or buildings.

105. The rocks on some portion of this district are different, geologically, from those on the northern side, but they are members of the same series, the Silurian and Cambrian, and will probably be equally innocuous as regards the water supply.

106. The nature of the surface is also generally very similar in the high portions of the district; lower down in the valleys of the Kent and its tributaries the streams pass over populous and cultivated land, and there are woollen and paper mills upon them, which defile the water, but these parts are below the lines of interception, and care would of course be taken not to admit any of this foul water into the conduits by which the main supply flows along.

107. Before leaving London, Dr. Frankland and myself thought it would suffice for this district to take a sample of eight gallons at the junction of the Sprint and Kent, a little above Kendal; but on visiting the spot for this purpose, I found the water so fouled by manufactories, by sheep-washing, &c., that it would give no idea of the upper drainage proposed to be taken. I therefore went higher up into the valleys and selected the following.

Sample H a.—Stockgill beck.

108. Two gallons, bottle No. 2, taken 23rd May above Ambleside, between the waterfall and the Bobbin mill.

Stream clear and colourless, vegetation on pebbles. Temperature 7°.

Sample H b.—Trout beck (Windermere).

109. The stream in this pretty valley comes down from near the summit of Kirkstone pass, and debouches into Windermere. The sample, two gallons, bottle No. 21, was taken 30 or 40 yards above the bridge at Trout beck village, and a little below the foot of the proposed reservoir.

Water transparent and white, with a little vegetation on the pebbles.

Sample H c.—Upper Kent.

110. Four gallons, bottles Nos. 9 and 32, taken 24th May at the Waterfoot bridge, just below the lower end of the proposed reservoir.

111. It was a powerful stream running 15,000,000 to 20,000,000 gallons per day, but as there is a reservoir in the upper part of the valley (made for the accommodation of the mills below), probably this was more than the normal flow.

The water was clear and colourless.

Leadworks in Kent Valley.

112. A little below the place where this sample was taken there is a lead mine, and some apparatus for washing the ore; but the whole thing is at present very insignificant, and it was not working when I was there. It is also below the point of interception, and the water from it, if fouled, could be prevented from interfering with the supply.

The only way in which it deserves consideration is, that this and other workings which, I am told, are being prosecuted in the neighbourhood afford evidence that lead exists about this part, and that the working for it might give trouble hereafter.

Sample H d.—River Sprint.

113. This sample, two gallons, bottle No. 7, was taken 24th May, at a point near the Sprint corn mill. This is much below the place where the stream would be intercepted, but the water looked clean.

I have, &c.

William Pole.

List of the Samples taken.

Those marked * are flood samples.
Those marked † contain water from mineral workings.

Distinguishing Letter.	Number of Gallons.	Number on Bottles.	Place.
A a	8	12 55 59 60	Thirlmere.
A b	2	40	Feeder to ditto.
A c†	2	47	Stream from lead works.
B a	2	51	Watendlath tarn.
B b	2	53	Naddle beck.
B c	2	49	Trout beck (Greta).
B c*	2	57	„ „ in flood.
B d*	2	58	Mosedale beck „
B e	2	46	Helvellyn gill.
B f	8	14 16 19 33	Upper Rothay.
C a	8	34 43 44 50	Haweswater.
C b	2	52	Measand beck.
D	2	37	Upper Lowther.
E	8	13 29 39 41	Lower Lowther.

APPENDIX B.

REPORT on the SELECTION of SAMPLES of WATER in the District of NORTH WALES.—By WILLIAM POLE, F.R.S., Mem. Inst. C.E. (*This Report is illustrated by the Map, Appendix E. 2.*)

SIR, Westminster, 19th June 1867.

1. I HAVE to report that in obedience to the instructions of the Commission I have visited the water-collecting districts of the Upper Severn, in North Wales, proposed by Mr. J. F. Bateman as sources of supply for London and other large towns.

2. I beg leave to refer to my former report of the 29th of May last for an explanation of the general manner in which I have carried out the instructions given me.

3. I was furnished with Mr. Bateman's published pamphlet on the subject, and a copy of his evidence before the Commission, and I received further explanations from him personally before my departure.

4. When I first arrived in the Northern district it had been raining heavily, and I was obliged to take the samples of the Vyrnwy and Banw in a state of flood. I then went to the Southern district, and as the weather had cleared up the streams there had had time to subside, and had apparently arrived at a fair weather condition.

It seemed to me very desirable that, if possible, all the streams should be taken under nearly similar circumstances, and as the weather still remained generally fine I paid a second visit to the Northern district, and obtained fine-weather samples there also. So that as regards these streams the Commission have samples taken in very different conditions, the comparison of which will doubtless be of considerable advantage.

I regret that this double work prevented me from going to Bala lake, samples from which were desired by Doctor Frankland.

5. Mr. Bateman's project comprises two separate water-collecting districts, each consisting of several drainage areas; and it will be convenient to classify the samples in accordance with these divisions, as follows:

Southern District.

M. Drainage area of the Severn Proper.
N. " " Tylwch.
O. " " Clywedog.
P. " " Tarannon and Ceryst.
Q. " " Carno.

Northern District.

R. Drainage area of the Banw and its tributaries.
S. " " Vyrnwy.

SOUTHERN DISTRICT.

6. The geological and mineralogical nature of the rocks in this district will be already well known to the Commission; I believe they are analogous to the rocks in the lake district of Cumberland and Westmorland, and they will, I have no doubt, be considered equally favourable for water collection.

7. The conformation of the land in the higher parts of the district is also of a favourable character, though it differs somewhat from that of the lake area. The hills, though generally steep and well marked, are of less altitude, and less abrupt and precipitous, their forms being more rounded; there is not much bare rock, but the surfaces are covered with grass, used for cattle and sheep pasture.

8. In descending the valleys cultivation begins, trees appear, and the population increases; and lower down, as the valleys widen out and the hills diminish, these features spread over a larger area. In some places attempts are made to extend the cultivation to a considerable altitude, but they do not seem very successful. In the lower and flatter parts of the district the land appears fertile and well tilled, but these form, I believe, only a small proportion of the whole drainage ground.

9. In the higher parts (as in the lake district) patches of peat moss frequently occur. I have seen in several places beds of peat of considerable extent being cut, and I find this forms almost the only fuel used by the residents on the higher ground. My samples in this district being all taken in fine weather, there was no brown colour in the water, but, by the analogy of the flood samples in the Vyrnwy and Banw, I presume the streams here also will be brown in flood time.

10. The lead workings and woollen factories have been mentioned as offering objections to the quality of the water in this district, and I have therefore thought it right to give particular attention to them.

11. I have marked on the accompanying map the places where the samples were taken, as also the position of the lead works and woollen factories mentioned in this Report.

LEAD WORKINGS.

12. I learned from Mr. Bateman's evidence that at the time he made his survey, some years ago, he found lead workings upon the Severn Proper, above Llanidloes, on which account he excluded that river from his scheme. On inquiring into this on the spot, however, I found that since that date the mining operations had undergone much change. It was said that the works on the Severn were no longer in operation, but that others had been established on nearly all the other streams comprised in this division of Mr. Bateman's plan. This subject therefore appeared of so much importance that I judged the Commission would desire me to ascertain the facts on the spot, and to report these facts to them. I first inquired at Llanidloes what lead works were in operation in or near the district, and then visited such of these as appeared most deserving attention, and I have given a summary of the information obtained at each place.

13. The lodes appear to vary considerably in composition. In the higher parts of the district, near Plinlimmon, they contain both lead and copper in a matrix of slate with quartz; in the lower parts the copper is not found, and the matrix consists almost entirely of slate. I am told, however, that in some parts calcareous and barytic spar occur as in Cumberland.

14. The general manner of preparing the mineral is the same as I have described for the Cumberland mines. No smelting is done in this part of the country.

Pant Mawr Mines.

15. These mines are not in the Severn district, but lie on the Upper Wye, about 3½ miles above the village of Llangurig. I thought it, however, right to go to see them, because they were mentioned in evidence before the Commission as having settling reservoirs, by which the injurious matter was said to be arrested, and the water sent down into the river clean and harmless.

I accordingly visited them on the 10th of June, but found that after being worked some years by the "Nanty Mining Company" they had been stopped some months since; the machinery had been sold and was being removed when I was there. The mineral had been extracted by steam power from the mine on the hill side, and had been passed down to a flat place on the bank of the river, where it had been crushed and washed in the usual manner.

I learned, by inquiries in the neighbourhood, that parties interested in the river had complained of the fouling of the water, and that litigation had taken place on the matter, in consequence of which the company had made settling tanks with the view of remedying the evil.

These consisted of a series of 15 rectangular ponds of various sizes, but occupying altogether about one-third of an acre, and each about four or five feet deep. The water passed through them successively and slowly, being decanted from the upper part of one tank into that next adjoining, so as to allow the sediment to deposit.

It was evident that these ponds had arrested much of the matter, as large heaps had been taken out of them. But I was informed by the clergyman of Llangurig (whose statements were confirmed by the landlord of the Bwlch Inn, a little higher up,) that the evil had not been perfectly remedied, for the water flowing down the river was still turbid, and the trout had still sustained injury. The clergyman, who, it appeared, was fond of fishing, had had his attention particularly directed to this subject, and had remarked that the effect of the poison on both trout and salmon was to give them a black colour, beginning at the tail. This effect had entirely ceased since the works had been stopped, and the fish had returned to the upper part of the river. I was informed that other lead workings had been opened higher up the valley, but that at present they were not of any important extent. The water in the river was perfectly clear and colourless.

Bryn-bos-du Mine.

16. This is said to be one of the most promising mines at present worked in the neighbourhood, and as I was led to believe it lay within the area of the Tylwch (or Dulas), one of the streams proposed to be appropriated, I went to see it on the 10th June.

I found it situated, not in a valley, as is most usual, but at a high level on a large bog forming the watershed between three streams, two tributaries to the Tylwch, and one running directly into the Severn. An old horse-gin pit has existed many years, but the present working is from another deep shaft drained and worked by steam power; and a new

one is being sunk, and a steam engine erected to work it. The mineral raised appears rich in ore, in a matrix of slate, without quartz or white spar.

The lead ore appears easily separated, and the separation and washing are done entirely by hand with very simple apparatus. Only a small quantity of water is used, the supply being raised from the shaft; after the washing it runs away very foul and of a dark slaty colour. It is allowed to flow into the bog, where its dirt appears to be absorbed, as I could not find traces of it in any of the streams.

The principal significance of this mine is as evidence of the existence of lead veins in this part of the district, and of the possibility of their being hit upon hereafter in places where their working would be of more importance to the drainage.

Llechwydd ddu, or Delife Lead Works.

17. These are the most important works in this part of the country. Mr. Hassard (Q. 1038) stated they were on the Clywedog, one of Mr. Bateman's streams, and the Ordnance map would appear to justify this assertion, but on visiting the works I found this was an error. At the place called on the map "Cwm Delife," although marked "Lead works," there is only a mine or shaft, and no "works" that I could see or hear of. The lead works lie on the north side of the hill called Llechwydd ddu, forming the water dividing ridge between the Severn and the Dyfi, and the drainage from them flows down the Twymyn to Llanbrynmair, and so by the Dyfi into the sea, a little north of Aberystwith.

The works are large, belonging to an association, one of whose principal members is Mr. John Bright, M.P. They are well laid out with all the most modern apparatus and machinery, and apparently very well managed. The work people were the best in appearance I ever saw in a mining district. About 200 hands are employed, and the produce, I was told, is about 25 or 30 tons per week, equivalent to about 20 or 25 tons of metallic lead, or something less than the Glendinning mine at Ullswater. The ore is not smelted on the premises, but is sent away for sale. A good deal of copper ore is also obtained along with the lead; this is put aside, and crushed and washed at intervals when there is sufficient quantity.

The manager, Captain Evans, took me over the works, and explained that complaints having been made of the fouling of the river below, the proprietors had laid out subsiding ponds at some distance down the valley, which I went to see. They are on the same principle as I have described at Pant Mawr, the fouled water being allowed to remain some time in each, and to decant from one to the other. It was evident that they did much good, by the quantity of deposit settling in them; and it is, I think, certain that any particles of lead ore which may come away must be deposited here. But some of the slaty and earthy matter appears to be so light, and to be levigated so finely, as still to remain in suspension, for I found the water flowing away from the last pond still turbid enough to render the bottom invisible at two or three inches depth.

Such a stream as this flowing into the rivers below, would, however, do very little mischief mechanically by deposit; and as to its effect on animal life, I noticed a fact which was strong evidence of its innocuousness, viz., that cattle were kept by a neighbouring farmer in the fields through which this stream ran, and sustained, apparently, no injury therefrom. I saw about 20 healthy looking young bullocks in one of the fields, some of whom were drinking from the stream just at its issue from the last settling pond.

There is still said to be some injurious effect on the fish, as complaints continue to be made, and this corroborates the testimony of the clergyman of Llangurig mentioned in paragraph 15.

Dwngwm Lead Works.

18. This mine immediately adjoins those of the Llechwydd ddu last described, but the shafts and works lie on the south side of the hill, and drain into the head of the valley of the Clywedog, one of Mr. Bateman's streams. The mines produce lead and copper ore, which is crushed and washed on the premises by machinery of the usual kind, but the works are much less extensive than those adjoining. There are no settling ponds, beyond the small usual "slime pits" used for completing the separation of the ore; but the fouled water from these, and the other parts of the machinery, runs directly into the stream.

I was told that the works had not been lately prosecuted with vigour, they sometimes employed about 60 hands. On the day I was there, the 11th June, only a few were at work, and no lead was being prepared; they were crushing and washing a stock of copper ore which had accumulated, and which it was desired to get rid of. The refuse water was but small in quantity, but it was very foul.

I took a sample of the water of the stream at "Stay little," about two miles below, but this only represents a exceptional state of things, and it must be borne in min that it is at any time possible that the mine might b worked vigorously, and might even rival the neighbourin one in extent and importance.

The Fan Mine.

19. This is an extensive working on the left bank of th Ceryst, about half a mile above the crossing of the road t Llanbrynmair, and just at the head of Mr. Bateman's gre reservoir. I visited it on the 13th June. It is a recent discovered lode, and is said to be successful; the machine is worked by a waterwheel of 50 or 60 feet in diameter, on the most modern and complete plan, and capable, I w told, of preparing nearly 20 tons of lead ore per wee though it did not appear to me that anything like such quantity was at present produced.

The refuse water from the separating pits runs into series of five settling ponds, each about 25 feet by 12, whe some of its matter is deposited. These have been put u lately, probably on account of complaints from the riv below, but they are much too small to be effective, and th flow into the river from them is very dirty. I have broug a sample of the river water contaminated with this refus taken about half a mile below the mine.

20. The above mentioned are the only works I thoug it necessary to visit, but there are several others whi have been worked lately and which may be resumed. T two mentioned by Mr. Bateman on the Severn must be, should think, the *Nant Melyn* or "Severn" mines, ne the source, and those of *Cwm rhicet* a little lower dow Both these are now stopped, and the machinery of t former is sold. Other mines, I believe, exist on or ne Plinlimmon, but I do not know their exact locality. The is a mine of some importance on the left bank of t Clywedog called *Bryndael*, but it is not now at work; a there is also another in the valley of the Ceryst, the nam of which I forget.

The mining speculations appear so uncertain and chang able that it is impossible either to reckon on the permanen of any mines that are working, or to foresee where wor may be prosecuted in time to come. The Ordnance Ge logical Survey shows that metallic lodes traverse the distri in various directions, and wherever these are found w must look for a possibility of operations being sooner later carried on.

21. It appears to me that the following inferences m fairly be drawn from the information obtained on the su ject of these mining works:—

1. It would appear useless to attempt to exclude th streams on which they occur. They already exist o several, and may exist on all.
2. From the places in which they lie, generally so high t the valleys, I should think it would be scarcely po sible to divert their drainage, particularly as the are few works sufficiently permanent to warrant a large expense being incurred with this object.
3. The fouling of the water may be either mechanical chemical. The former is, I think, amenable to ea treatment. Great pains are taken to extract from th mineral all the metallic ore it contains; and I shou think, therefore, very little of this can pass off. believe the matter carried down consists almost e tirely of the lighter earthy substances, separated fro the ore and held in mechanical suspension by th washing water passing away.

   Where there is no inducement to be careful, a gre quantity of this matter is thrown or allowed to pa into the stream, such being the easiest way to get r of it. But the practice of mines better managed lea to the belief that if the plan of subsiding ponds we sufficiently carried out, and all possible care take to stack the débris on spoil banks, the matter passin away might be reduced to a very small amount, an to a very light kind, which would probably subsi in large reservoirs without doing any harm; or necessary even this might be arrested and the wat rendered perfectly limpid by some simple mode filtration, which I was told by one of the minin managers had already been partially tried.
4. The question of chemical contamination by matt dissolved in the water I am unable to offer any opinio upon. The chemists will doubtless report on the fe samples I have brought from this and the lake di tricts; but the composition of the various metalli lodes appears to be very diversified, and probably n result derived from the analysis of one or two woul be of general application. I have been told of th suspected existence, in some cases, of arsenical salt and in others of some free acid, deleterious to fis

but very little definite information is to be obtained in the districts themselves. The question has been agitated in several places, by parties interested in the river fisheries, and probably the Commission might obtain useful evidence from some of their officers. I should imagine that if any noxious matters should be found dissolved, it might not be beyond the power of chemical and metallurgical science to find a remedy, if its application would be worth the trouble; but it must be borne in mind that the quantity of impurity must, in most cases, be extremely small when compared with the large dilution by the flood waters of the streams.

Woollen Manufactories.

22. This part of the country is noted for its manufacture of Welsh flannel, and the mills have been mentioned as defiling the water, but the more important of them are close to Llanidloes, below the intercepting conduits of Mr. Bateman's water collection.

I visited some of these works, where I find the wool is carded, spun, and woven into flannel in the usual way. The only part of the process likely to injure the water is the cleaning or "fulling" of the flannel when it is made. To extract the grease and dirt it is treated with fuller's earth and beaten by heavy wooden mallets worked by machinery, being well washed with water during the process; the water running away must, of course, be injured, although it did not look dirty. In some of the mills I noticed that the wool was washed before carding, but this does not seem to be general.

23. I could only ascertain the existence of four works within Mr. Bateman's drainage area, and all these I saw. The two most important are on the left bank of the Clywedog: the upper one, Glyn mills, belonging to Mr. Clayton, and situated about a mile and a half above the junction with the Severn, are large works employing about 100 hands, the other one is smaller and a little lower down.

The "factory" on the Severn, marked on the Ordnance map, has ceased to work; at Cae-yn-y-coed, a little lower down, I found one with a fulling mill adjoining, but the whole thing is very small.

And there is a still smaller carding mill on the Tylwch, on the road to Llangurig, about two miles from Llanidloes, but there is nothing done here to dirty the water.

24. I do not attach much importance to these mills, as I believe it would be easy to divert the drainage from them so as to prevent it from fouling the streams.

25. I now proceed to explain where the various samples from this district were taken.

M. Severn Proper.

26. I have already stated that this was excluded by Mr. Bateman, on account of lead works upon it when he made his survey; but as these works are not now in operation, I have thought it right to take a sample.

It is a fine stream, draining an area of about 20 square miles of the highest and most favourable land in the district, and it was running, when I saw it, a large quantity for the area, namely, above 20,000,000 of gallons per day. There is a small woollen factory, mentioned in paragraph 23.

Sample M,

Eight gallons, bottles Nos. 64, 81, 92, and 93, was taken, 13th June, just above the factory. The water was beautifully clear and colourless.

N. Tylwch.

27. This stream drains about 25 square miles and runs into the south side of the Severn, a little above Llanidloes. The area seems flatter and more cultivated than that of the rivers rising more to the westward.

Two railways have lately been made in this valley, the "Mid-Wales," which runs from Llanidloes by Tylwch and Pant-y-dwr to Rhyader and South Wales; and a line called the "Manchester and Milford," which, branching off from the last one, ascends the tributary stream to the westward, and dips into the valley of the Wye at Llangurig, where it stops. It has never been worked.

There is a lead working on the edge of the drainage, and a small woollen factory in the district, but neither of them do any harm to the water.

Sample N,

Four gallons, bottles Nos. 70 and 71, was taken, 12th June at the crossing of the road to Llangurig. The stream was clear and colourless, running 8,000,000 to 10,000,000 gallons daily.

O. Clywedog.

28. This stream, like most of the others in this division, drains about 25 square miles. It is proposed to form a small reservoir upon the upper part of it near the village of "Stay a little," where a favourable site exists for the purpose.

On this river there are two mining works, at Dwngwm, near the head of the stream, and at Bryndael; the latter was not at work when I was there, and the former was working, exceptionally, copper ore. (See paragraph 18.)

Sample O a,

Two gallons, bottle No. 6, was taken just above "Stay a little," and about two miles below the Dwngwm works. The stream was running 2,000,000 to 3,000,000 gallons daily. Water slightly turbid.

There are also two woollen factories on the stream. (See paragraph 23.)

Sample O b,

Eight gallons, bottles 74, 75, 77, and 86, was taken, 13th June, just above the upper factory. The water was transparent and colourless, and was running, like the Severn, above 20,000,000 of gallons daily.

P. Tarannon and Ceryst.

29. These two rivers, in the lower part of their course, traverse a flat, expanded valley below Trefeglwys, and join together shortly before entering the Severn. The drainage area is about 25 square miles.

The valley narrows at its lower end, and Mr. Bateman proposes to throw a dam across at this point, which will convert the whole of the Trefeglwys valley into an immense lake for storage. Into this lake the water from the whole of the other rivers will be conducted, and from it the conduit will issue to convey the supply away.

The Tarannon is the more important stream. It is unaffected by any accidental causes of impurity.

Sample P a,

Six gallons, bottles Nos. 24, 69, 80, was taken on the 12th June, from the bridge on the main road near Trefeglwys. Water clear and colourless, running about 6,000,000 gallons per day.

The Ceryst is much smaller, and is much fouled by the refuse from the "Fan" mine. (See paragraph 19.) There are also other mines upon it which were not working when I was there.

Sample P b,

Two gallons, bottle 94, was taken on the 13th June, at the crossing of the road, about half a mile below the Fan works. Water turbid and dirty, running about 3,000,000 gallons per day.

Sample P c,

Eight gallons, bottles Nos. 65, 66, 67, 78, was taken, 12th June, a little below the junction of the two rivers. The water was dirty, bottom not visible at more than about 12 inches deep. This may have been caused partly by the mine, but also partly by running over the clay bottom of the flat valley.

Q. Carno.

30. This stream drains about 25 square miles. The railway to Aberystwith runs up the valley. I have not heard of any mines or factories upon it.

Sample Q,

Eight gallons, bottles Nos. 61, 62, 63, 68, was taken, 12th June, from the point where it is proposed to tap the stream, about half a mile above the little village of Pont-y-ddolgoch. Water clear, but a slimy deposit on the pebbles. Quantity small for the area, only about 3,000,000 or 4,000,000 gallons per day.

NORTHERN DISTRICT.

31. The general remarks in paragraphs 6 to 9 will apply to this district also, which is of a very similar character. I think, however, that in some parts, as for example, near Can Office, on the Banw, there is more cultivation; and in others, as near Lwydiarth Park on the Vyrnwy, there are more trees.

On the other hand this district, as far as I know, is entirely free from manufactories or mineral workings.

32. I have had the good fortune to obtain two sets of samples from this district, the first in flood, the second about a week afterwards in fair weather.

R. Banw and its Tributaries.

33. This part of the district is composed of the drainage ground of the river Banw, and its tributaries above Rhyd-y-gro, comprising about 50 square miles.

Three reservoirs are to be formed in this area, two upon the river itself, and one on the tributary stream called the Eira, falling into it a little below Can Office.

Dr. Frankland had suggested that an 8-gallon sample of water taken below the junction of the large tributary, the Eira, would suffice for this district. But as there was a little difference in appearance between the flood water of the Banw Proper and that of the tributary, I slightly varied the proposal by taking four gallons of each of the streams, and four gallons of the combined river beyond the junction. These can either be mixed together or examined separately, as the chemist may prefer.

Sample R a.—Banw above Eira.*

34. This sample, four gallons, bottles Nos. 28 and 30, was taken on the afternoon of 6th June, a little above the inn at Can Office. The weather had been wet for some days; it had rained heavily in the morning, and the river was full and rapid. It was running 12 inches deep (with an approaching velocity of two or three feet per second) over a weir 60 feet wide, and with a mill race in addition, giving about 130,000,000 gallons per day, equal to about one-third of an inch per day over its whole drainage area.

The water was brown and rather turbid, but the bottom could still be seen through a depth of 9 to 12 inches of water.

Sample R b.—Eira.*

This sample, four gallons, bottles 8 and 37, was taken the same day as the last, at a point about a quarter of a mile above the junction.

The valley of this stream appeared (as far as I could judge without going up it) flatter and lower than that of the Banw, and the water was somewhat different in appearance. The brown colour was rather less deep, but the water was more muddy and turbid; the bottom being hidden at about six inches deep.

The quantity appeared almost as great as in the Banw, but I had no means of gauging it easily.

Sample R. c.—Banw and Eira combined.*

36. This sample, four gallons, bottles Nos. 26 and 31, was taken the same day, just above the bridge of Llanerfyl. Water brown and turbid, bottom not visible at greater depth than six inches.

37. I went up the main valley, as far as the water dividing ridge, but did not perceive any necessity for taking additional samples. All the streams had the same brown colour up to their sources, or at least to the highest points to which I could trace them, and I believe most of them rise in the peat mosses from which this colour is derived.

But in the upper parts of the valley these streams though brown were always transparent. It was only in lower ground that the small rivulets, draining from the rainfall over the alluvium of the flatter lands, introduced the turbidity and slight dirtiness remarked where the samples were taken.

38. I had the opportunity of watching these streams for some little time after I took the samples, when the weather was clearing up, and found them change very rapidly.

The Banw, for example, at Can Office, which on the 6th at 2½ p.m. was running 130,000,000 gallons per day, had at 3½ p.m. on the 7th diminished to about 90,000,000. It had, moreover, lost its turbidity and become transparent, but had retained its brown colour. At 8½ p.m. the same day it was reduced to something above 50,000,000, and at 8 a.m. on the 8th to under 30,000,000.

Similar changes had taken place in the Eira and at Llanerfil bridge; the brown colour remaining fully preserved in all cases.

The rapid change in appearance led me to think that, though probably the peaty brown colour may be a constant characteristic of the streams in rainy weather, the turbidity is only a transient superficial effect following immediately from actual rain, and disappearing very soon. If this is so, when the water is stored in large reservoirs the sediment would probably soon subside and cause no trouble.

Second Sample R c.—Banw and Eira.

39. Eight gallons, bottles Nos. 72, 73, 76, 79. This second sample was taken at Llanerfyl bridge on the 14th June, eight days after the former one, during which time there had been no rain to speak of. The Banw above Can Office had dwindled to less than 10,000,000 gallons, and the Eira to less than 5,000,000. The water was quite transparent and colourless in both streams.

S. Upper Vyrnwy.

40. Mr. Bateman proposes to make use of a large gathering ground of about the same area as the last at the head of the river Vyrnwy, extending down to Pont Hagel, a large reservoir being formed on the main stream, as shown in Mr. Bateman's pamphlet.

At Pont Hagel the water is to be diverted from its natural course and turned by a tunnel into the lowest reservoir of the last-mentioned district above Rhyd-y-gro.

It appeared sufficient for this district to select one place for the example, namely, the point at which it is intended to carry the water away.

Sample S.—Vyrnwy.*

This sample, eight gallons, bottles Nos. 15, 17, 22, 25, was taken at Pont Hagel on the 7th June. The weather had been rainy, but had cleared up that day.

It was a fine, large, and rapid river, running probably above 200,000,000 gallons per day. The water was brown but transparent.

Second Sample S.—Vyrnwy.

This second sample, eight gallons, bottles Nos. 82, 83, 95, 96, was taken on the 14th June, from the same place. The stream had diminished to about one-tenth of what it was before, and the water had become perfectly colourless.

I have, &c.

William Pole.

Arthur Lennox, Esq., Secretary,
Royal Commission on Water Supply.

APPENDIX C.

SUPPLEMENT to REPORT on the SELECTION of SAMPLES of WATER in the WELSH DISTRICT.—By WILLIAM POLE, F.R.S., Mem. Inst. C.E.

SIR, Westminster, 13th July 1867.

1. IN paragraph 4 of my Report on Mr. Bateman's district I stated that from the necessity of going twice to the Vyrnwy and Banw, I was unable at that time to get samples from Bala Lake, which were included in my instructions.

2. The drainage ground of this lake does not form part of Mr. Bateman's scheme, but it was considered desirable, both by him and by Dr. Frankland, that samples of its waters should be collected along with the others, in order to ascertain the effect which storage in a large reservoir would have on waters considered analogous to those of the Severn district, and supplied from the same hills.*

3. I therefore visited the lake on the 2nd of July. The weather had remained fair from the time the other Welsh samples were taken, till the 1st of July, on the evening of which day, as well as on the 2nd there was some rain, but not enough to have much apparent effect on either the quantity or quality of the streams. The lake was very low, and the quantity flowing both in and out very small for the drainage area.

4. The district appears to be generally of the same nature as those selected by Mr. Bateman, except that the hills around it are higher. I should think the water flowing from it would be of very nearly the same character. On the higher grounds peat is said to exist, which is cut and burnt for fuel, and the streams are said to be brown in rainy weather.

5. I took samples from the lake itself, and from four of its principal feeders.

6. The water from the lake, which I may distinguish as—

Sample Bala (a.)

(Eight gallons, bottles Nos. 20, 86, 87, 88,) was taken in a boat, about a quarter of a mile off the village of Llan-y-cil.

Sample Bala (b.)

(Four gallons, bottles Nos. 23, 91,) was from the Twrch near the road-crossing at Pandy. This is the principal feeder which comes from the south, and whose drainage area is contiguous to that of the Vyrnwy. There is a small woollen mill and a tanyard on the lower part of this stream.

Sample Bala (c.)

(Two gallons, bottle No. 89,) is from the Dwfrdwy, near the bridge at Llanwchllyn. Stream slightly tinged brown, with white scum.

Sample Bala (d.)

(Two gallons, bottle No. 10,) is from the Afon Llyn at Pont Lliw. There is a gold mine on this stream at Castell Carndochan, and I am told that at certain times, when the quartz is crushed, the stream is rendered milky. There was nothing doing when I was there, and the water was clear.

Sample Bala (e.)

(Two gallons, bottle No. 18,) is from the Afon Llafar, at the road-crossing. Water slightly turbid, with white scum.

7. I should mention that a railway (from Bala to Dolgelly) is now being constructed on the south bank of the lake, the rails will, I believe, be only about 2 feet above the highest flood level (or 6 or 7 feet above drought level) and therefore this will be an obstacle to any raising of the lake with the view of increasing its capacity as a reservoir.

I am, &c.,
WILLIAM POLE.

Arthur Lennox, Esq., Secretary,
Royal Commission on Water Supply.

* The Bala Lake was proposed as a source of supply to Liverpool so long ago as 1846, by Mr. Rawlinson, C.B., and the proposal has been lately renewed, in a modified form, by Mr. Duncan, the engineer of the Liverpool Corporation Waterworks.

APPENDIX D.

REPORT on the CHEMICAL QUALITY of SAMPLES of WATER collected in NORTH WALES and in the LAKE DISTRICT of CUMBERLAND and WESTMORELAND.—By Dr. E. FRANKLAND, F.R.S., and Dr. ODLING, F.R.S.

To the Royal Commission on Water Supply.

MY LORD DUKE AND GENTLEMEN,

IN compliance with your instructions we have made an analytical examination of numerous samples of water from North Wales and from the lake districts of Cumberland and Westmoreland collected for the purpose by Mr. William Pole, F.R.S., whose report on the topographical and geological character of the respective gathering grounds has been already presented to the Commission.

The samples appear to have been most judiciously and carefully collected. Their large number, and the variety of meteorological conditions under which they were taken, have enabled us to make a very complete investigation into the quality of the water likely to be obtained from each of the districts.

The following table contains a list of the samples transmitted to us by Mr. Pole, the dates of their collection, the estimated flow of the streams at the time of collection, and our own remarks on the appearance of the samples when they arrived, and of the residues which they left on evaporation.

WELSH SAMPLES.

Place of Collection.	Date of Collection.	Estimated daily run of Water when Sample was taken.	Appearance of Samples, Remarks, &c.
Southern District.	1867.	Gallons.	
River Severn - -	June 13	20,000,000	Clear and colourless.
Tylwch - - -	„ 12	9,000,000	Clear and colourless. Residue left on evaporation slightly brown.
Upper Clywedog -	„ 13	2,500,000	Colourless and slightly milky. Residue left on evaporation slightly brown. Contains water from mineral workings.
Lower Clywedog -	1867. June 13	20,000,000	Clear and colourless. Contains water from minera workings.
Tarannon - -	„ 12	6,000,000	Clear and colourless, leaving a slightly brown residue on evaporation.
Ceryst - - -	„ 13	3,000,000	Milky, from fine suspended matter. Contains water from the washing apparatus of the Fan mine.
Tarannon and Ceryst, just below junction.	„ 12	3,000,000	Full of fine suspended matter.
Carno - - -	„ 12	3,500,000	Clear and colourless.
Northern District.			
Banw in flood -	„ 6	130,000,000	Clear but very yellow.
Eira in flood - -	„ 6	130,000,000	Clear and brownish yellow.
Banw and Eira in flood, after junction.	„ 6		Slightly turbid, and of a deep yellow colour, leaving a very brown residue on evaporation.
Banw and Eira after subsidence of flood.	„ 14	15,000,000	Clear and colourless, leaving a very slightly brown residue on evaporation.
Vyrnwy - -	„ 14	20,000,000	Clear and colourless, leaving a very slightly brown residue on evaporation.
Vyrnwy in flood -	„ 7	200,000,000	Clear and of a deep yellow colour.
Bala Lake and Feeders.			
Bala Lake - -	July 3		Clear, very slightly yellow.
Mixed samples from four feeders to Bala Lake.	„ 3		All the samples were clear, three were colourless, while the fourth had a slightly yellow tinge.

CUMBERLAND AND WESTMORELAND SAMPLES.

Place of Collection.	Date of Collection.	Estimated daily run of Water when Sample was taken.	Appearance of Samples, Remarks, &c.
Thirlmere District.	1867.	Gallons.	
Thirlmere Lake -	May 13		Clear and colourless, leaving a slightly brown residue on evaporation.
Main feeder to Thirlmere.	„ 13		Clear and of a slightly brown tinge.
Stream from Lead-works running into Thirlmere.	„ 13		Milky but colourless, leaving a white residue on evaporation.
Proposed additions to Thirlmere District.			
Watendlath Tarn -	„ 14		Clear, brownish tinge.
Naddle Beck - -	„ 13		Clear and colourless, leaving a brownish residue on evaporation.
Troutbeck (Greta)	„ 15		Clear and of a bright yellow colour, leaving a brownish residue on evaporation.
Troutbeck (Greta) in flood.	„ 11		Clear yellowish brown, leaving a nearly black residue on evaporation.
Mosedale Beck in flood.	„ 11		Clear yellowish brown, leaving a nearly black residue on evaporation.
Helvellyn Gill -	„ 13		Clear and colourless.
Upper Rothay -	„ 22		Clear and colourless, leaving a somewhat brown residue on evaporation.
Haweswater District.			
Haweswater Lake -	„ 16		Clear and colourless, leaving a slightly brown residue on evaporation.
Measand Beck -	„ 16		Clear and colourless, leaving a very slightly brown residue on evaporation.
Proposed additions to Haweswater District.			
Upper Lowther -	„ 16		Clear and colourless, leaving a brown residue on evaporation.
Lower Lowther -	„ 15	50,000,000	Clear and colourless, leaving a slightly brown residue on evaporation.
Ullswater District.			
Ullswater Lake -	„ 21	40,000,000	Clear and colourless, leaving a slightly brown residue on evaporation.
Airy Beck - -	„ 17		Clear and colourless.
Glenridding Beck -	„ 18		Milky even after filtration, leaving a white residue on evaporation.
Stream running into Glenridding Beck from Lead-works.	„ 18		
Grisedale Beck -	„ 18		Clear, slightly yellow.
Goldrill Beck -	„ 18		Clear and colourless. Contains water from mineral workings.
Proposed additions to the Ullswater District.			
Dacre Beck - -	„ 20		Clear, with a slightly brown tinge.
Stockgill Beck -	„ 23		Clear and colourless.
Troutbeck (Windermere).	„ 23		Clear and colourless, leaving a white residue on evaporation.
Upper Kent - -	„ 24	20,000,000	Clear and colourless, leaving a white residue on evaporation.
River Sprint - -	„ 24		Clear and colourless, leaving a very slightly brown residue on evaporation.

After the arrival of the samples of water they were allowed to stand for at least two days, to deposit suspended matter. About a quart of each water was then poured carefully into a flask, and the observations upon the colour and transparency, contained in the above table, were made. The appearance of each sample of water, as given above, may therefore be regarded as that which it would present if viewed in a quart decanter of flint glass.

We considered that, by thus allowing time for the deposition of suspended matters, the appearance of many of the waters would more nearly approach to that which they would present after storage in a lake or reservoir. It will be remarked that many of the samples mentioned by Mr. Pole as turbid at the time of collection are described by us as clear. In some cases also there is a discrepancy in our statements as regards colour. This is doubtless owing partly to the different conditions, as regards depth of water, &c., under which the observations were made, and partly, perhaps, to an alteration of tint during transit.

Chemical Examination of the Waters.

Each sample of water submitted to analysis was poured from the stoppered glass bottle in which it had been collected in such a manner as not to disturb any sediment. The total solid residue was determined by evaporating one litre (1,000 grams) (or in some cases half a litre) of the water to dryness in a platinum capsule placed upon a steam bath. The residue after being dried at 100° C. until it ceased to lose weight was then weighed in the usual manner.

There is no process known by which the accurate determination of the organic matter contained in potable waters can be effected, but, by a method recently devised by one of us, we have determined the amount of carbon and of nitrogen entering into the composition of the organic matter contained in the several samples submitted to us. For this purpose a litre of each water was acidified with sulphurous acid and evaporated to dryness. The dry residue was then burnt in vacuo with chromate of lead and oxide of copper, and the carbonic acid and nitrogen determined as gases. The nitrogen existing as nitrates and nitrites was estimated by evaporating nearly to dryness one litre of each water, transforming the chlorides into sulphates by the addition of sulphate of silver, mixing the resulting concentrated liquid with an equal volume of sulphuric acid in an inverted glass tube filled with mercury, and then agitating the mixed liquid with the mercury for a few minutes. The whole of the nitrogen present in the water as nitrites and nitrates was thus transformed into nitric oxide gas, the volume of which was then determined. The ammonia was estimated by Nessler's test, and the hardness by Clark's soap test.

These analytical operations were performed upon all the waters; but certain samples, such as those taken from the lakes and more considerable rivers, and of which larger quantities (eight gallons) were collected, were submitted to the more searching examination of a complete analysis. The mineral constituents in these samples were quantitatively estimated by the usual processes of inorganic analysis; whilst the gases held in solution were determined by boiling the waters for one hour in vacuo and collecting the expelled gases over mercury. The carbonic acid was determined by absorption with caustic potash, the oxygen and nitrogen by explosion with excess of hydrogen.

In the determination of the gases we were much indebted to the assistance of Mr. M'Leod, who performed the manipulatory operations with great skill and accuracy; every number in the annexed tables is the mean of at least two distinct and well accordant determinations.

The following tables exhibit the results of these analyses.

They are to be read thus:—100,000 lbs. of the water of the river Severn, collected on June 13th, left on evaporation a solid residue, which when dried at 100° C. weighed 3·369 lbs. The above quantity of water contained in solution solid mineral ingredients, from which the following substances were extracted by analysis ·417 lb. of lime, ·244 lb. of magnesia, ·147 lb. of potash, ·816 lb. of soda, 1·066 lb. of sulphuric acid, ·147 lb. of carbonic acid, ·200 lb. of silica, ·823 lb. of chlorine, ·007 lb. of nitrogen (which existed in the water as nitrates and nitrites), ·003 lb. of ammonia. The organic matters present in the same weight of water contained ·005 lb. of nitrogen and ·2 lb. of carbon. This amount of water yielded ·009 lb. of ammonia on ebullition with permanganate of potash. It also contained ·009 lb. of carbonate of lime or its equivalent of other soap destroying constituents, none of which was removed by boiling the water for half an hour. Finally 100 volumes of the water of the Severn contained 2·2 volumes of dissolved gases consisting of 1·412 vol. of nitrogen, ·641 vol. of oxygen, and ·147 vol. of carbonic acid.

Additional Observations by Dr. Frankland.

In connexion with the various analytical determinations contained in the above tables, the following additional explanations and observations are offered:—

I.—Total Solid Residue.

Apart from the quality of the ingredients contained in potable waters, the proportion of solid residue left on evaporation is a rough indication of the comparative purity of such waters; for, although in cases where this residue is considerable, it by no means follows that a sample with a smaller amount is, for domestic purposes, superior to one containing a larger quantity, yet it may be safely asserted that waters leaving large residues on evaporation are unfit for domestic use, whilst those containing very small residues are, on this account alone, well adapted to such purposes, and but very rarely contain amongst their impurities any which are seriously objectionable. Besides their general superiority for domestic purposes, waters leaving small residues on evaporation possess great advantages over less pure waters for a large number of manufacturing purposes, especially for feeding steam boilers are the purer waters invaluable, as their use precludes the formation of incrustations which not only seriously interfere with the transmission of heat from the fuel to the water, but are believed to be not unfrequently the cause of disastrous explosions.

The Welsh Waters leave on evaporation residues which vary from a minimum of 3·37 parts in 100,000 to a maximum of 9·6 parts in 100,000. It must be remarked, however, that this maximum is attained only in the case of a small stream (the Ceryst) running, at the time of collection, only about 3,000,000 gallons per day, and fouled by much suspended matter from the Fan mine. In a storage reservoir this suspended matter would subside, and the resulting clear water would doubtless leave considerably less solid residue on evaporation. This remark will also apply to the united waters of the Tarannon and Ceryst, containing 6·4 parts of solid residue in 100,000 parts of water.

On the other hand, the water of the Lower Clywedog, running 20,000,000 gallons daily, contains 8·1 parts of solid residue in 100,000 parts, and, being clear when collected, would not deposit much of this matter on standing in a reservoir, but although the residue is large when compared with the purest samples from the proposed gathering grounds, it nevertheless compares favourably with the waters at present supplied to London, which leave on evaporation solid residues varying during the year 1866 from 20·2 to 40·4 parts in 100,000.

The Cumberland and Westmoreland Waters leave on evaporation residues varying from a minimum of 2·14 parts to a maximum of 13·6 parts in 100,000; this maximum, however, is exhibited by a sample (the Dacre Beck) which stands alone as regards impurity amongst the waters of this district. Its exceptional character has already been pointed out by Mr. Pole in his report on the collection of the samples, and the analytical results support his recommendation that this beck should be excluded from Messrs. Heman's and Hassard's scheme.

Omitting this sample, the next as regards amount of residue is that taken from the Lower Lowther, which contains 9·29 parts of solid matter in 100,000 parts of water; but the Lower Lowther is intended to be used chiefly for compensation water, and Mr. Pole has pointed out a modification of the proposed conduits, by which, whilst the purer water of the Upper Lowther (containing only 5·1 parts of residue in 100,000) would be utilized, the lower part of the river would be altogether excluded from the scheme. Although the water of the Lower Lowther is by no means of bad quality, yet it is so much inferior to the remaining sources of this district as to fully justify Mr. Pole in considering its exclusion desirable. If we omit this sample and also leave out of consideration the milky stream which flows from the Glenridding lead mines, the maximum amount of solid residue occurs in the Troutbeck (Greta) water, which contains 6 parts of solid residue in 100·000 parts. With the exceptions just mentioned, therefore, the waters of the Cumberland and Westmoreland district leave a smaller residue on evaporation than those of the Welsh district. The residues left by the waters of the three great lakes included in the Cumberland scheme are remarkable for their insignificance, viz.:—

Thirlmere	- -	2·66 parts in 100,000
Haweswater	- -	3·56 „
Ullswater	- -	3·63 „

The storage of waters in large lakes or reservoirs appears, as a rule, to diminish the proportion of solid residue as compared with that contained in the feeders of such lakes. Unfortunately in Mr. Bateman's district there is no such lake, and we are thus deprived of a fair basis of comparison between the quality of the water now stored in the three Cumberland lakes and that of the water which would be delivered from the large reservoirs contemplated in Mr. Bateman's scheme. On this account we have examined the water of the Bala Lake and its feeders, which, although just outside Mr. Bateman's district, drain the same geological formation as the northern Welsh district. A comparison of the solid residue of the feeders of this lake with that of the water of the lake itself not only exhibits the purification effected in lakes and reservoirs but also indicates that the Welsh water, after storage, would not be inferior in purity, as regards solid residue, to that of the Cumberland lakes. The residues in the waters of Bala Lake and its feeders are as follow:—

Bala Lake	- -	2·79 parts in 100·000
Average of four feeders of ditto	- -	4·10 „

So far, therefore, as total solid residue is concerned, the above analytical results promise a water supply from either district fully equal in purity to that of any town in the United Kingdom.

II.—The Mineral Constituents.

The solid residue left on the evaporation of potable waters consists partly of mineral and partly of organic matters. Unless the amount of residue be considerable but few of the individual mineral constituents are of much interest, we have, therefore, only submitted the more important samples of water to the searching investigation required for the separate determination of each of these constituents. Of the mineral matters met with in potable waters those belonging to the following three classes claim our chief attention.

1. Substances which decompose soap.
2. Substances which are more or less derived from the decomposition of nitrogenous organic matters previously existing either in the water or in the soil with which the water has been in contact.
3. Substances of a poisonous character, such as compounds of the metals, arsenic, copper, and lead.

The first class of mineral matters above enumerated consists of the hardening or soap destroying constituents of waters. The chief substances of this class are the salts of lime and magnesia. These salts decompose soap, forming curdy and insoluble compounds, containing the fatty acids of the soap and the lime and magnesia of the salts. So long as this decomposition goes on the soap fails to produce a lather, and is consequently useless as a detergent; but when all the lime and magnesia salts have been decomposed by the soap, the slightest further addition of the latter produces a lather when the water is agitated. In the above tables the hardness of the different samples of water is expressed in parts of carbonate of lime, or of its equivalent of other hardening salts, contained in 100,000 parts of the water, each part of carbonate of lime contained in this quantity of water being commonly termed a degree of hardness.* Each degree of hardness indicates the destruction of about 12 parts of the best hard soap by 100,000 parts of water. Hard water is, however, not only objectionable from an economical point of view, but by rendering efficient ablution and thorough cleanliness difficult of attainment, it doubtless indirectly affects the health of communities to which it is supplied. From the well-known action of hard water upon soap, the process of washing the skin with such water may be thus described. First, the skin is wetted with the water, then soap is applied; the latter soon decomposes all the hardening salts contained in the small quantity of water with which the skin is covered, and there is then formed a strong solution of soap which penetrates into the pores of the cuticle. Such is the process which goes on whilst a lather is produced in washing, but now the lather requires to be removed by rinsing it away with water, and in this operation the pores of the skin become plugged up with the curdy matter which results from the action of the hard water upon the soap solution occupying those pores. The operation of washing with soap and hard water is thus analogous to that used by the dyer or calico printer when he wishes to fix a pigment upon any tissue. He first introduces into the tubes of the fibre (of calico, for instance) a liquid, containing in solution one of the ingredients necessary for the formation of the insoluble pigment, this is followed by another liquid containing the remaining necessary ingredient also in solution; the insoluble pigment is then produced within the very tubes of the cotton fibre, and is thus imprisoned in such a manner as to defy removal by subsequent washing. The process of ablution in hard water is essentially one of dyeing the skin with the white insoluble, greasy, and curdy salts of the fatty acids contained in the soap. The pores of the skin are thus more or less blocked up, and it is only

* The degree of hardness more usually employed by chemists is that first proposed by Dr. T. Clark, viz., one grain of carbonate of lime, or its equivalent in one imperial gallon of water or one part in 70,000 of water. The degrees in the above table harmonize better with the decimal arrangements of the rest of the analytical results; they are readily converted into Clark's degrees by multiplying by seven, and then moving the decimal point one place to the left.

because the insoluble pigment produced is white that such a repulsive operation is tolerated. To those, however, who have been accustomed to wash in soft water the abnormal condition of the skin thus induced is for a long time extremely unpleasant.

In the year 1851 this subject received the careful consideration of a Government Commission, consisting of the present Master of the Mint, Dr. W. A. Miller, and Dr. A. W. Hofmann.* I entirely agree with these chemists in their condemnation of hard waters for the supply of towns, and beg to refer to their report for the grounds upon which this condemnation is based. Having had the opportunity of comparing a six years' experience of the soft water supplied to Manchester with a subsequent 10 years' experience of the hard water of London, I have to record that the soft water was, for all purposes, preferred by every member of my family. On removing from Manchester to London, the repugnance to drink the hard water of the latter city, even though filtered, was quite as marked as that which I have sometimes noticed in the case of persons who make the transition in the opposite direction. Moreover, when water is excessively hard from the presence of carbonates of lime and magnesia, a portion of these salts is deposited on exposure to the air, and the water reaches the consumer milky and turbid. This is frequently the case with the chalk waters delivered in London. A constant supply of hot water has become almost a necessity in every household, but great difficulties are thrown in the way of its attainment by the use of hard water, owing to the formation of thick calcareous crusts in the heating apparatus. This evil is so great where the heating of the water is effected in a coil of pipe, as practically to prevent in London the use of this most convenient mode of heating water. The water in my kitchen was for several years heated in this way, but it was found that three months' use sufficed to deposit so much calcareous matter in the pipe as to reduce the bore of the latter to $\frac{1}{4}$th inch. The coil had, therefore, to be taken to pieces at intervals of three months, and the hard deposit removed by a tedious and expensive process, which, moreover, so far injured the copper pipe itself as to render its frequent renewal necessary.

An inspection of the above analytical tables shows that the samples of water both from the Welsh and Cumberland districts are very soft, being, generally speaking, of about the same degree of hardness as those supplied to Manchester and Glasgow. Leaving out of consideration, for reasons above given, the water from the Dacre Beck in Cumberland, which has 8° of hardness, and from the Lower Lowther, the following table gives the comparative hardness of the Welsh, Cumberland, and London waters:—

	Maximum.	Minimum.
	°	°
Welsh waters - - -	3·0	0·4
Ditto, exclusive of Bala Lake -	3·0	0·7
Cumberland waters - -	2·9	0·7
London - - - -	28·8	14·4

The hardness of the London waters is chiefly of the kind known as *temporary* hardness; it is caused by carbonate of lime, the larger proportion of which is gradually deposited on boiling the water for half an hour. The temporary hardness of the London waters varies from 9·9° to 19·1°, whilst the *permanent* hardness (that is the hardness remaining after boiling for half an hour) oscillates between 3·4° and 9·7°. On account of this softening of temporarily hard water by boiling, temporary hardness is considered to be less objectionable than the same amount of permanent hardness. There is reason to believe, however, that the advantages of temporary over permanent hardness have been considerably overrated. Practically, water used for domestic purposes is, even when used hot, either not heated to the boiling point, or is boiled for too short a time to remove more than a small proportion of its temporary hardness. Thus, water drawn from the kitchen boilers of a dwelling house and of the Athenæum Club was usually nearly as hard as the cold water with which they were supplied, as is seen from the results of the following experiments:—

* Report by the Government Commission on the chemical quality of the supply of water to the metropolis.

It has been objected with reference to the use of soft water that such water is liable to attack and dissolve the lead of the pipes through which it is conveyed, or of the cisterns in which it is stored; and secondly, that soft water would exclude from the diet of its consumers the calcareous matter necessary for the formation and renewal of the bones.

Reasons are given below for concluding that, as regards the first of these objections, no fear of lead contamination need be entertained from the introduction either of the Welsh or Cumberland waters into London. The second objection to the use of soft water is equally fallacious; first, because the amount of lime contained in the water at present drunk by an inhabitant of the metropolis is only a minute fraction of that which he takes in other articles of food and drink; and secondly, because observation and experience show that hard water is not necessary to a full development of bone in man. It cannot be said that the stalwart natives of the soft water districts of the Highlands of Scotland are deficient in bony development.

The second class of mineral constituents above mentioned consists of substances derived partly from the atmosphere and partly from the decomposition of nitrogenous organic matters previously existing either in the water or in the soil with which the water has been in contact. In view of the opinions now very generally entertained, with regard to the propagation of certain forms of disease by means of spores or germs contained in excrementitious matters, the search for this class of impurities is second only in importance to that for actual sewage contamination, because, although these substances are in themselves innocuous, unless present in excessive quantity, yet, when contained in a water in more than a certain proportion, they betray the previous contamination of the water by sewage or by manured land. The nitrogenous organic matters contained in sewage or manure undergo slow oxidation, and conversion into mineral compounds when mixed with water; their carbon is converted into carbonic acid, and their hydrogen into water. These products can no longer be identified in the aërated waters of a river, spring, or lake, but the nitrogen is transformed successively into ammonia, nitrous acid, and nitric acid; the two latter combine with the bases contained in most waters, and, together with the ammonia, constitute a record of the sewage or other analogous contamination to which the water has been subject. With certain corrections presently to be mentioned, the analytical determination of the nitrogen contained in these mineral compounds furnishes the previous history of the water as regards its contact with decomposing nitrogenous organic matters. In the monthly reports furnished by me to the Registrar General on the Metropolitan water supply this determination has been employed for the estimation of the previous sewage contamination of a water, expressed in parts of average filtered London sewage, which, if thus completely oxidised in a river, would yield a like amount of nitrogen in the form of ammonia, nitrites, and nitrates. For this purpose average filtered London sewage may be taken as containing 10 parts of combined nitrogen in 100,000 parts, as deduced from the numerous analyses of Hofmann and Witt, and of Way and Odling. The number so obtained as the previous sewage contamination of a water requires, however, a correction, since rain-water itself contains combined nitrogen as ammonia, nitrite of ammonia, and nitrate of ammonia. The amount of these substances present in the rain which falls at Rothampstead has been determined by a series of monthly analyses made independently, on the one hand by Messrs. Lawes and Gilbert, and on the other by Professor Way, and extending over two years. The results of these chemists give as the average amount of nitrogen in the forms of ammonia, nitrite of ammonia, and nitrate of ammonia, ·0985 part in 100,000 parts of rain-water. This corresponds to 985 parts of previous sewage contamination, which has hitherto been deducted from the previous sewage contamination of the London waters, as determined by analysis. But the experience gained in the examination of the Welsh and Cumberland waters teaches that this deduction is far too large. The maximum amount of ammonia contained in the 42 samples of water examined by us is only ·008 part in 100,000, whilst the average amount of nitrogen in the form of nitrous and nitric acids observed by Messrs. Lawes, Gilbert, and Way, and this in thunder rain only, was but ·024 part in 100,000. It may, therefore, be safely assumed that the maximum amount of combined nitrogen, derived by natural waters from aërial sources, does not exceed ·024 + ·008 = ·032 part in 100,000, which gives the number 320 to be deducted from the previous sewage contamination as determined by analysis.

Absolutely pure water is unknown in nature, for, as just stated, even rainwater is contaminated, and its descent down the precipitous slopes of the Welsh and Cumberland mountains cannot fail to bring it into contact with the droppings of sheep, cattle, and birds. The amount of impurity so contracted is, however, infinitesimal, but when

ıe water receives the drainage from cultivated land, the ·sidues of oxidised nitrogenous organic matters become im-ıediately appreciable to chemical analysis. Thus the stream ›rmed by the junction of the Tarannon and Ceryst, hich Mr. Pole describes as traversing a flat expanded alley, exhibits unmistakeable signs of previous sewage ntamination, for it contains no less than ·068 part of trogen in the form of nitrates and nitrites, corresponding, cording to the mode of corrected estimation just given, to 60 parts of oxidised London sewage in 100,000 parts of ıe water.

The amount of nitrogen contained in the Welsh waters the form of ammonia, and of nitrites and nitrates, only ceeds the amount contained in rain-water in the following ses:—

	Nitrogen in the form of ammonia, and of nitrites and nitrates in 100,000 parts.	Corresponding previous sewage contamination in 100,000 parts.
ıarannon and Ceryst	·068	360
eryst - -	·053	210
arno - -	·051	190

ut of 24 samples from the Cumberland district only one ntained these mineral compounds of nitrogen in quantity ger than that found in rain-water; this was the sample llected from the Upper Kent, which contained ·046 part nitrogen in the form of ammonia, and of nitrates and trites in 100,000 parts, corresponding to 140 parts of pre-ous sewage contamination in 100,000 parts. The follow-g table extracted from the reports of the Registrar General ows the condition of the present metropolitan water pply as regards these mineral compounds of nitrogen, d the previous sewage contamination thereby indicated. is table contains the maximum and minimum analytical sults for the months of June, July, August, September, d October last, the estimations of previous sewage con-mination being corrected, as above described, by the duction of the number 320 instead of 985.

A comparison of this table with the corresponding deter-inations in even the worst of the Welsh and Cumberland aters shows the striking superiority of the samples from ıe last two sources. The unfavourable position which ıe Kent Company's water takes in this comparison is markable, since this water is derived from wells sunk to the chalk, and might therefore be presumed to be ore than usually free from contamination of this kind; ut the phenomenon excites less surprise when it is membered that the chalk of the London basin receives large amount of soakage from cultivated land; secondly, ıat the chalk wells of Woolwich Arsenal betray symp-oms of connexion with the river Thames; and, thirdly, ıat the chalk itself is, according to the recent researches f Bechamp, filled with living microscopical organisms. he presence of large quantities of nitrates in the chalk aters of the Kent Company is by no means exceptional; ese salts exist in still larger quantity in the chalk waters f Grays (South Essex Company's water), Worthing, and Vatford. Mr. Dugald Campbell states that the water of ıe shallow chalk wells invariably contains a notable uantity of nitrates, whilst that of the deep chalk wells ontains scarcely a trace.

The third class of mineral substances, viz., those of a oisonous character, such as compounds of the metals rsenic, copper, and lead, have been carefully searched for ı those waters which are contaminated by mineral orkings. In only three cases have we been able to etect any of these impurities, viz., in the Glenridding eck, the stream from lead-works flowing into Glenridding eck, and the stream from lead-works flowing into Thirl-ıere, which contain lead, but in such excessively minute uantity as to allay any apprehensions of injurious conse-uences resulting from the admission of these waters into he lakes or reservoirs. Indeed reasons are given below for trongly recommending that these streams from mineral orkings should not be diverted, but, under certain restric-ions, be freely admitted into the storage waters.

III.—The Organic Constituents.

Of all the impurities present in potable waters organic matters are admitted on all hands to possess, from a sanitary point of view, the highest importance and most especial interest. These substances may be divided into two great classes, viz., 1st, organized organic matters, and 2nd, unorganized organic matters. The detection and identification of the first of these classes does not properly belong to the province of the chemist; considering the superlative importance, however, with which it is generally regarded in connexion with the propagation of certain forms of disease, it is singular that it should have hitherto received so little attention from the naturalist, and that, notwithstanding the strong and general suspicion of their existence, no animal or vegetable germs connected with the production of disease in man have been identified in water. It is obvious that all organized organic matters in water must be in suspension and not in solution, but it by no means follows that such matters can therefore be removed by filtration. The minute ova of animalcules have been observed to pass through filters, and it has been proved* that the suspended matter in the rice-water evacuations of cholera patients cannot be removed by filtration from water which has become contaminated with such matter. These facts, together with the certainty that dilution with large volumes of water does not, as in the case of unorganized substances in solution, render organized germs innocuous, acquires great significance in view of the prevalent theories of the propagation of cholera, typhoid fever, and other diseases.

The class of unorganized organic impurities in potable waters is much more amenable to chemical research, and has in fact always attracted the special attention of the water analyst. Speaking of these substances in their report to the President of the General Board of Health, on the Metropolis Water Supply in 1856, Messrs. Hofmann and Blyth made the following important remarks (p. 5): "It is "now generally admitted, that the substances which con-"stitute the organic matter of water act injuriously by no "means in consequence of being poisonous themselves, "but by undergoing those great processes of transforma-"tion called decay and putrefaction to which all vegetable "and animal matter is subject when no longer under the "control of vitality, either in plants or animals. These "putrefactive processes either give rise to the formation of "poisonous bodies, or they act simply as ferments, genera-"ting similar processes of decomposition in the substances "composing the animal organism. Now with special refe-"rence to the last mode of action, it is well established by "general experience that *nitrogenous* substances are infi-"nitely more liable to undergo putrefaction than organic "bodies from which nitrogen is absent. And hence the "very general and correct opinion that the deleterious "character of organic matter in water is proportionate to "the amount of *nitrogen* which it contains. Could this "nitrogen be estimated with any degree of accuracy, such "an estimate would certainly afford the most satisfactory "element in the examination of organic matter." At the time the above remarks were written no method of making this estimation of nitrogen was known; indeed, it is only quite recently that the process which we have employed for the determination both of organic nitrogen and of organic carbon was devised.

The Welsh Waters contain an amount of organic carbon which varies from ·200 part in 100,000 parts of the water of the Severn to 1·040 part in 100,000 in the flood waters of the united rivers Banw and Eira. All the samples which contain more than ·35 part of organic carbon in 100,000 are, with the exception of the upper Clywedog, more or less coloured, and they are all, with the same exception (the upper Clywedog, running at the time of collection 2,000,000 or 3,000,000 gallons daily) flood samples. The colour is doubtless due to peaty matter in solution, and it is believed that such peaty matter is to a great extent deposited or otherwise got rid of when the water is stored for some time in a lake or resevoir. This opinion receives confirmation from the above results of the analyses of lake waters, all of which are colourless, or very nearly so, and contain only a small amount of organic carbon; thus the water of the Bala Lake contains but ·227 part of organic carbon in 100,000 parts, whilst the waters of Thirlmere, Haweswater, and Ullswater contain at the maximum only ·194 part in 100,000. On the other hand, when the amount of peaty matter in solution is excessive, this purification in lakes does not appear to take place to a marked extent; thus, the water which flows out of Loch Ness is of a deep yellow brown colour, and numerous other Scotch lakes might be cited as exhibiting the same phenomenon. Although the peaty matter dissolved in water cannot be said to be positively injurious, yet, inasmuch as it contains traces of organic nitrogen, it cannot be pronounced absolutely innocuous.

* Weekly return of the Registrar General for the week ending 17th November 1860.

The amount contained in the water of Loch Katrine as supplied to Glasgow, and which is represented by ·256 part of organic carbon in 100,000 parts, ought not to be greatly exceeded in water used for domestic purposes.

The organic nitrogen contained in the Welsh waters varies from 0 to ·013 part in 100,000 parts, the latter proportion occurring in the flood water of the Banw. The other samples from this district which exhibit a somewhat high proportion of organic nitrogen are flood samples from the Eira, and from the combined streams Banw and Eira ·012 and ·011 part in 100,000. The mixed waters of four feeders of Bala Lake also contained ·010 part in 100,000. Judging from the effect of the storage of water in Bala Lake in diminishing organic nitrogen, it may be anticipated that the combined waters of this district when delivered from the proposed reservoirs would not contain more than ·005 part of organic nitrogen in 100,000, and would probably contain less, for the Bala Lake contains only ·001 part, although the united waters of its four principal feeders yield no less than 10 times this proportion.

In addition to the organic nitrogen as thus determined by direct analysis we have also estimated the amount of ammonia which is evolved from the waters by prolonged ebullition with a strongly alkaline solution of permanganate of potash, the ammonia previously existing in the water being first expelled by ebullition with carbonate of soda. This method has been recently proposed by Messrs. Wanklyn and Chapman as a means of determining the organic nitrogen in waters. In our hands this process has yielded somewhat irregular results. As a rule, which is however by no means without exceptions, the organic nitrogen so inferred is considerably less than that obtained by direct analysis, and this is markedly the case with those waters which contain a comparatively large amount of organic nitrogen; thus, the flood water of Troutbeck (Greta) gave us by analysis ·068 part of organic nitrogen, whilst the same water when boiled with alkaline permanganate gave only ·016 part. Whilst therefore this process is valuable as a ready qualitative method of ascertaining the presence of organic nitrogen in waters, we do not think that, in its present form, it can be relied upon for the determination of the actual amount of this element.

The Cumberland Waters contain an amount of organic carbon which varies from ·066 part to 1·059 part in 100,000. It will thus be seen that whilst the minimum proportion of this element is much smaller than that contained in the Welsh waters (·200 part in 100,000), the maximum is almost identical, and also occurs in a flood sample. With this and one other exception, however, the Cumberland waters contain markedly less organic carbon than the Welsh samples; but, in making this comparison, it must be borne in mind that out of 24 samples of Cumberland water only two were flood samples, whilst out of 16 samples from Wales four were flood samples. Excluding these flood samples in both cases, the mean proportion of organic carbon in the samples from the two districts, independently of the flow of the streams, is as follows:—

Welsh waters	·289
Cumberland waters	·211

The organic nitrogen contained in the Cumberland waters varies from 0 in Ullswater lake and Glenridding Beck to ·068 part in 100,000 in the flood water of Troutbeck (Greta). The Mosedale Beck in flood also contains ·042 part in 100,000. In his report on the collection of the last two waters, Mr. Pole, judging only from the appearance of the streams, suggests their rejection from the scheme; our analytical results strongly confirm this suggestion. Excluding the flood samples of both districts, and leaving out of consideration as before the volumes of water from which the samples were taken, the average proportion of organic nitrogen in the specimens from the two districts is—

Welsh waters	·004
Cumberland waters	·006

It is a remarkable circumstance that the waters of the Cumberland district which are described by Mr. Pole as contaminated by mineral workings, at the time of collection, contain but very small proportions both of organic carbon and nitrogen. Thus, the milky water flowing down Glenridding Beck from the extensive leadworks on the flanks of Helvellyn contained but ·116 part of organic carbon, whilst it was absolutely free from organic nitrogen. An inspection of the following numbers shows at a glance the extreme purity as regards organic matter of the streams containing milky water from the crushing engines of mines:—

	Organic carbon.	Organic nitrogen.
Glenridding Beck	·116	·000
Steam from leadworks flowing into Thirlmere	·066	·001
Goldrill Beck	·262	·001

In the Welsh district the small proportion of organic carbon in waters flowing from mineral workings is not so evident, but the amount of organic nitrogen is remarkably low. The only samples which at the time of collection were actually receiving the finely-suspended matter from this source were the following:—

	Organic carbon in 100,000 parts.	Organic nitrogen in 100,000 parts.
Ceryst	·209	·000
Upper Clywedog	·544	·000
Lower „	·242	·001
Tarannon and Ceryst	·304	·001

The water of the Upper Clywedog, though containing as much as ·544 part of organic carbon in 100,000 parts, is perfectly colourless, the peaty matter in solution having been apparently blanched by the fine suspended detritus from the Dwngwm lead mine. This removal of colouring matter from water by fine suspended mineral matter is seen on a magnificent scale in Switzerland, where Alpine torrents carrying the fine mud produced by the attrition of glaciers upon rocks, enter the lakes milky and foul, but, having deposited their suspended matter in these reservoirs of subsidence, emerge clear and transparent, and of that magnificent blue-green tinge (properly belonging to absolutely pure water) which is so much admired in the Rhone as it flows from the Lake of Geneva, and in the Limmat leaving the Lake of Zurich. An observant tourist cannot fail to remark striking indications of this clarifying action in the lakes of Ullswater and Coniston. The blue-green tint of water freed from colouring matter is distinctly perceptible for several miles around the mouths of the streams coming down from the Glenridding leadworks, in the one case, and from the extensive mines in Coniston Old Man in the other. I consider, therefore, that, so far from the diversion of these streams being desirable, their admission into the lakes and reservoirs would be attended with very considerable advantages, in the removal of peaty matter from the storage water.

It has been already stated that even in cases where we have detected lead in these milky streams, the amount is so infinitesimal as to allay the apprehensions of the most fastidious as regards any deleterious effect upon the consumer of the water with which these streams are allowed to mingle. The finest portion of this detritus doubtless possesses the most active clarifying effect, and it is, therefore, desirable, as recommended by Mr. Pole, that the grosser particles, which would silt up the reservoirs without producing any correspondingly beneficial effect, should be separated in subsiding tanks, and, it need scarcely be added, that care should be taken to prevent the excretions of the miners from gaining access to these streams.

In order to ascertain the effect of an admixture of milky water from mineral workings with a water strongly coloured with peaty matter, the deep yellow flood water of the Banw and Eira was agitated with an equal volume of the Glenridding Beck water. The deep yellow of the peaty water was very materially diminished beyond the mere effect of dilution, and on evaporation the residue was of a light yellow colour, whilst that of the flood sample alone was dark brown.

IV. The Gaseous Constituents.

The gaseous constituents contained in the waters, both of the Welsh and Cumberland districts, are of the kind usually found in good soft potable waters, which invariably contain a smaller proportion of gases than is met with in hard waters abounding in carbonates of lime and magnesia. The latter frequently retain, by the chemical affinity of their dissolved salts, a larger amount of carbonic acid than they could absorb by the process of solution alone. In fact, the carbonic acid thus chemically united with the carbonates of lime and magnesia can scarcely be said to be in the state of merely dissolved gas, although it is expelled along with the actually dissolved gases on the prolonged ebullition of the water. Recently distilled water contains about the following amounts of dissolved gases in 100 volumes:—

Nitrogen	1·133
Oxygen	·617
Carbonic acid	·105
	1·855

Collected near the great natural condensers, the waters of both Wales and Cumberland contain, as might be expected, but little more air in solution than recently distilled water. In their long transit to London, however, they would doubtless become much better aërated, but even then they would contain a much smaller proportion of carbonic acid than the waters at present supplied to the metropolis, and would consequently appear less sparkling

an the latter. Sparkling waters, highly charged with rbonic acid, are generally preferred by the public, even en they owe their briskness to extensive contact with caying organic matter. On the other hand, it is not true at soft waters are necessarily vapid; no draught of water n be more delicious than that which is obtained from the blic drinking fountains of Glasgow, supplied from Loch trine, although 100 volumes of this water contain, as I ve ascertained, only the following gaseous constituents:—

Nitrogen	1·731
Oxygen	·704
Carbonic acid	·113
	2·548

The Welsh Waters contain in 100 volumes the following portions of the same gases, viz.:—

	Minimum.	Maximum.	Mean.
trogen	1·226	1·412	1·323
ygen	·566	·642	·612
rbonic acid	·107	·335	·227
	1·899	2·389	2·162

In waters which are free from putrescent organic matters e proportion of oxygen to nitrogen in the dissolved gases ght to be nearly as 1 : 2. In the Welsh waters the proion varies from 1 : 2·03 in the Bala Lake water to 2·43 in the Lower Clywedog.

The Cumberland Waters contain in 100 volumes the lowing proportions of gases, viz.:—

	Minimum.	Maximum.	Mean.
trogen	1·310	1·551	1·424
ygen	·667	·749	·726
rbonic acid	·085	·793	·281
	2·062	3·093	2·431

The proportion of oxygen to nitrogen varies from 1 : 1·87 the Lower Lowther to 1 : 2·08 in Ullswater. The Cumrland waters are therefore somewhat better aërated than e Welsh samples, and they also exhibit a higher proporon of oxygen to nitrogen.

V. Action upon Lead.

We have ascertained carefully the behaviour of every mple of water in contact both with bright and clean lead d with the metal in that tarnished condition which it asmes after exposure for a few days to the atmosphere. The sults of our observations, which are contained in the preding analytical tables, prove conclusively that soft waters o not necessarily act upon lead, and that whilst many of ie samples examined by us attack the metal when its surce has been recently scraped, comparatively few have any ction upon the tarnished metal, and probably none would ttack the leaden pipes through which any of the waters at resent supplied to London have been transmitted.

The conditions which determine the character of water as egards its action upon lead have hitherto been involved in uch obscurity, notwithstanding that they have repeatedly een the subject of investigation. The Government Comission of 1851 on the water supply of the metropolis stablished the fact that the presence of dissolved oxygen nd the absence of more than three volumes of carbonic cid in 100 volumes of water, are amongst the conditions ecessary to cause the water to attack lead. The whole of he present water supply to the metropolis is perfectly proected from acting upon lead by the large amount of disolved and combined carbonic acid which it contains. Nevertheless, there are obviously other conditions involved n the problem, for every sample of water, the gases from vhich we have examined, from both districts contains disolved oxygen, and the proportion of this gas existing in he different samples is remarkably uniform, whilst not one of them contains an amount of carbonic acid even remotely pproaching that which is necessary to protect it, and yet ome of these waters act powerfully upon bright lead, and onsiderably upon the tarnished metal, whilst others are ntirely without action upon either.

In the course of some recent experiments upon this subect, the writer observed that a sample of distilled water vhich acted violently upon lead completely lost this power by momentary contact with animal charcoal; further investigation of the cause of this phenomenon, proved the protecting material to be phosphoric acid which is contained in the animal charcoal in the form of phosphate of lime. Acting upon the suggestion afforded by these experiments, he has very carefully examined for phosphoric acid the water of the Upper Kent which is eminently distinguished for its violent action upon lead, and the water of the river Vyrnwy which has not the slightest action upon lead even when placed in contact with a bright and freshly cut surface of the metal for 24 hours. The result of this examination established the fact that the water of the Vyrnwy contained an appreciable amount of phosphoric acid, whilst not the slightest trace of this acid could be detected in that of the Upper Kent. It has also been ascertained that the admixture of an equal volume of the Vyrnwy water with that of the Upper Kent greatly reduced, although it did not altogether prevent its action upon the bright metal. The compounds of phosphoric acid are therefore obviously eminently efficient in protecting water from action upon lead, and whenever such action is feared, the foregoing facts point to a most simple and efficient remedy, viz.:—the passage of a certain proportion of the water through animal charcoal. As the merest trace of the phosphate of lime is dissolved by the water, the hardness of the latter is not thereby sensibly increased. It may, however, be confidently stated that no danger on this score need be apprehended from the introduction of water from either district into the metropolis, as it will be seen that but a very small number of the waters act upon tarnished lead—a condition of the metal which soon ensues in new lead pipes. Unquestionable as the reasons for this conclusion appear to be, it is satisfactory to find them supported by many years experience on a large scale. Amongst the waters which we have examined from both districts there is not one which acts more powerfully upon lead than that supplied to Glasgow from Loch Katrine, and yet it is believed that no symptoms of lead poisoning have ever been observed in that city since its introduction seven years ago. It has been sometimes stated that although the Loch Katrine water acts powerfully upon bright lead it does not attack tarnished lead, and also that whilst the water acts violently upon lead as it issues from the lake, it loses this power during its transmission through some 25 miles of conduit on its way to Glasgow. Neither of these statements accords with the writer's own experience. He has examined samples taken nearly simultaneously from the lake and at Glasgow and finds that both samples act with equal energy, and attack both bright and tarnished lead. It is thus evident that even a water of this character can be safely delivered to a large community. Probably the lead pipes are slightly acted upon at first, but a protecting film soon coats their inner surfaces and prevents further attack. This is known to be the case at Manchester where the water acts slightly upon new pipes, but the action soon ceases.

The Welsh Waters may be classified in regard to their action on lead as follows:—

	Action on bright lead.
3 samples	Very powerful.
1 „	Powerful.
3 „	Considerable.
4 „	Slight.
5 „	None.
	Action on tarnished lead.
2 samples	Considerable.
14 „	None.

The Cumberland Waters may in the same way be thus classified:—

	Action on bright lead.
6 samples	Powerful.
6 „	Considerable.
4 „	Slight.
8 „	None.
	Action on tarnished lead.
1 sample	Slight.
23 samples	None.

In conclusion, it only remains to compare the results of the foregoing analyses with those yielded by the waters at present supplied to the metropolis, and in order to facilitate the comparison on the present as well as on future occasions, it will be convenient to throw the data into the form in which they are expressed in my monthly reports on the metropolitan waters published by the Registrar General. The numbers for the London waters are taken from the reports for May, June, July, August, September, and October last. The waters supplied to Glasgow, Manchester, and Lancaster are also included in the comparison.

* This high number occurred only once in a sample of water collected from the West Middlesex Company's mains. The impurity was abnormal, and was occasioned by the fracture of one of the mains and the consequent access of sewage to its contents, whilst the pressure was removed in accordance with the intermittent system of service.

The numbers in the above columns all refer to 100,000 parts of each water. The table is to be read thus:—100,000 lbs. of Thames water, as delivered by the five metropolitan companies drawing their supplies from that river, contained in the last six months a quantity of solid impurity amounting to 29·84 lbs. in the maximum, 23·70 lbs. in the minimum, or to 26·78 lbs. on the average. The organic matter constituting a portion of this impurity contained on the average ·275 lb. of carbon and ·011 lb. of nitrogen. This solid impurity also contained an average amount of ammonia equal to ·007 lb., and of nitrogen, in the form of nitrates and nitrites, ·192 lb.; whilst the total amount of *combined* nitrogen in every form averaged ·213 lb. The above quantity of water had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 1,751 parts of average filtered London sewage. By gradual oxidation, partly in the pores of the soil, partly in the Thames or its tributaries, and partly in the reservoirs, filters, and conduits of the companies, this sewage or other similar contamination had been entirely converted into comparatively innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of Thames water contained on the average 19·3 lbs. of carbonate of lime, or an equivalent quantity of other soap-destroying ingredients.

The foregoing table permits the following conclusions to be drawn:—

1. The total solid impurity in the Welsh and Cumberland waters is very much less than that in the purest of the waters now delivered by the London companies. On the average of the whole number of samples it amounts to about one-fifth of that contained in the London waters; but if we may be permitted to assume that the water actually delivered from large storage reservoirs in the two districts would have a degree of purity equal to that now collected in the lakes, it would scarcely contain more than one-tenth of the solid impurity of the present London supply.

2. The amounts of organic carbon and organic nitrogen in the present and proposed supplies do not differ to such an extent as to compel a decided preference for either.

3. In the inorganic forms of combined nitrogen, viz.—ammonia, and especially nitrates and nitrites, both the proposed supplies exhibit great superiority over the waters at present delivered in London. The Welsh waters do not contain on the average more than about one-tenth, and the Cumberland waters only about $\frac{1}{10}$th, of the amount contained in the London water, whilst the lake waters of both districts are almost absolutely free from this form of impurity. The significance of such impurity has already been remarked upon, as bearing witness, when the contamination exceeds a certain proportion, of previous contact with decaying organic matters, generally of animal origin. This excess of mineral nitrogenous impurity, to which the name *previous sewage contamination* has been applied, exhibits in the most striking light the vast superiority of the proposed over the present water supply. In the whole of the Cumberland and Westmoreland district this contamination only occurs in one instance, viz., the Upper Kent, and that to a small extent only. In the Welsh samples there are only three instances, whilst not one of the lake waters of either district exhibits this contamination. On the other hand the waters at present supplied to London betray an average amount of this impurity, which would be produced by the oxidation of from 1 to more than 3 per cent. of their volume of average London sewage.

4. With two exceptions all the waters from the proposed sources of supply are of sufficient softness, their hardness averaging considerably less than $\frac{1}{10}$th of that of the softest at present supplied to London.

5. No apprehension of lead poisoning need be entertained from the use of the waters from either district in the ordinary lead service pipes of the metropolis.

6. The waters from the proposed sources compare favourably with those which have been substituted for the old supply in Glasgow, Manchester, and Lancaster.

E. Frankland, F.R.S.

P.S.—Substantially I agree with the preceding observations of my colleague Dr. Frankland in everything that relates to the character of the waters of Wales and Cumberland which we have examined. Taking them altogether, these waters are excellently suited for the supply of towns. They are of fair appearance, taste, and aëration. They contain but a small proportion of dissolved mineral matter, and are extremely soft, but unlike many soft waters, exert no sensible action upon ordinary lead. They contain moreover but small proportions of organic nitrogen and carbon (organic matter), and have not been at any time subjected to sewage contamination.

Although London is at present provided with an agreeable, and in my opinion perfectly wholesome water, still it is evident that for general town supply a soft water such as that of Wales or Cumberland is upon the whole more suitable than a somewhat hard water such as that of the Thames and Lea; and, further, that a water which neither contains nor has received sewage impurity is at any rate preferable to a water which certainly has received, even though it does not actually contain any such impurity.

I take this opportunity of acknowledging the advantage which our joint investigation has derived from my colleague's observations upon the subject of the action or non-action of soft water upon lead; and still more from his much desiderated invention of a trustworthy and delicate process for estimating the nitrogen of the organic matter of water.

William Odling, M.B., F.R.S.

APPENDIX E.

(REPRINT OF PAMPHLET.)

Metropolis Water Supply.

On the Supply of Water to London from the Sources of the River Severn.—By John Frederic Bateman, C.E., F.R.S., F.G.S., &c.

The extraordinary increase of London and other large towns in this country is one of the most remarkable circumstances of the age, and may well attract the serious consideration of all who are interested in the prosperity, the sanitary condition, and the well-being of large masses of human beings. London now contains, within the metropolitan district, a population of no less than 3,000,000 souls. It has trebled itself since the beginning of the century, doubled itself within the last 40 years, and is just half as large again as it was 20 years ago. Should it continue to progress at the same rate it will, in another 20 years, contain no less than 4,500,000 inhabitants, to which must be added the vast and still more rapidly increasing population of the surrounding suburban districts.

Amongst the many subjects of anxious consideration which are involved in the maintenance of so large and closely-concentrated a population, the question of their water supply is probably the most important, inasmuch as upon its quality and abundance, the health and comfort, and indeed the very existence of the population—as a town population—depend, and because it is absolutely impossible for individuals to help themselves in case of deficiency.

London is supplied by eight different water companies, who jointly pour into the metropolis and its immediate suburbs an average daily quantity of about 100,000,000 gallons of water, of which about one half are abstracted from the river Thames, and the other half from the original sources of the New River Company, from the river Lea, and from deep wells on the easterly and northerly sides of London, and from the river Ravensbourne on the south. Upon the present gross population the average supply is about 30 gallons per head per day. If the increase in the quantity supplied were only to keep pace with the increase in population, the daily supply 20 years hence would be about 150,000,000 gallons; but as the habits of modern life conduce to more liberal use of water, there can be little doubt that 160,000,000 or 180,000,000 gallons per day will then be too small a quantity for the wants of the population.

The rate of increase in the quantity consumed may be judged of by the facts that in 1850 the gross daily quantity delivered was 44,383,332 gallons; in 1856 it had reached "upwards of 81,000,000 gallons per day, having been nearly doubled in the short space of six years,"* and now, in 1865, it is about 108,000,000.

The water companies have up to this time fully met the demands upon them, and since the year 1852, when, in consequence of the then unsatisfactory state of the supply, they were compelled to go higher up the rivers and effect various other improvements, they have expended nearly 4,000,000*l.* sterling in extensions of works. In consequence of this outlay, notwithstanding the great increase in the

* *Vide* Report to Right Hon. William Cowper, by Messrs. Austin, Ranger, and Dickens, on Metropolis Water Supply, 21st July 1856.

number of their customers, the per-centage rate of their dividends has, with one or two exceptions, remained nearly unaltered, and in a pecuniary point of view, therefore, they are now little better off than they were previous to that time.

Short as the period is since the completion of the various improvements and alterations they were called upon to make, several of the companies are already looking anxiously for additional means of supply, and though those companies which are enabled to withdraw water from the Thames have still a considerable margin left, it will be insufficient to meet the wants of many years. By the various Acts which were passed in 1852, authorising the withdrawal of the water from this river, the maximum quantity which they were empowered to take was 100,000,000 gallons per day, and there are, I believe, many days in which between 60,000,000 and 70,000,000 gallons per day are abstracted, although the average daily abstraction, including Sundays, does not amount to 60,000,000. It is notorious also, that the volume of the Thames has been so diminished of late years, and has otherwise undergone such material changes, as to create great anxiety in the minds of those interested in the maintenance of the river. When the Acts of 1852 were passed it was estimated that the minimum quantity of water at Hampton was 362,000,000 gallons per day, and this minimum has been habitually considered, in round numbers, as 400,000,000. During the month of September in this year (1865), the river has been carefully measured above the waterworks at Hampton, and the gross daily quantity for a considerable period together has scarcely exceeded 300,000,000 gallons. The residents on the banks of the river below the lowest point at which water is taken by the water companies have this year been loud in their complaints of the diminution and pollution of the water, and have been holding public meetings for the purpose of seriously considering what steps are to be taken for maintaining the volume and purity of the stream.

There is no adequate source within the means of any of the existing companies to which they can resort. They will hardly be permitted to increase the draught from the Thames, and any supplies which could still be obtained from the chalk basin on which London lies are altogether insufficient to meet future demands. It is therefore matter of urgent necessity that the question should be broadly and liberally considered, while there is yet time to execute the requisite works for obtaining a full and ample supply from other distant sources, before those still at the command of the companies are exhausted.

What would be the effect of such a deficient supply of water as many of the towns in the kingdom have recently been labouring under, in a city containing above 3,000,000 people, it is fearful to contemplate, and no narrow considerations of parsimonious economy ought to be allowed to interfere with the execution of any large and comprehensive scheme which would ensure for very many years a full and abundant supply.

With the example of such judicious outlay, and such successful results as have attended a wise expenditure in this direction at Manchester and Glasgow, it can surely never be that London will hesitate in spending a like sum in proportion to its means, for obtaining a similar supply of water, if it can be shown that it is possible to obtain it.

But beyond the mere quantity of water, there are other considerations of equal importance. Purity is as essential to the well-being and sanitary condition of the town; and the quality of softness especially, is most important on the ground of economy in the use of the water. When the Loch Katrine water was introduced into Glasgow it was estimated, on the most careful computation, that the economy which resulted in domestic establishments was equal to the whole rate paid for the water supply, or 36,000*l.* a year upon a population of 400,000 persons; and this was by the substitution of water of about 1 degree of hardness as compared with the water of the Clyde, which varied from 7 to 9 degrees of hardness. The saving in trading establishments where water was used for delicate operations could not be fully estimated; but in the article of soap alone it saved five-eighths of all that had been previously used, and, probably, a like proportion in dye-drugs and chemicals.

Assuming these figures to be correct (and the facts were most carefully worked out at the time), the saving to the inhabitants of London, by substituting water of equal quality with Loch Katrine in lieu of the hard water of the sources from whence the supply is now derived, averaging from 12° to 16° of hardness by Dr. Clarke's scale, would not be less than 400,000*l.* per annum. Were the water no harder in quality than the Clyde, the saving would be, in proportion to the population, about 300,000*l.* per annum; but considering that the London water is twice as hard as the Clyde, the calculation of 400,000*l.* a year is certainly below the truth.

I will not dwell upon the importance of soft water in its bearing on the health of the inhabitants, although I believe it is well established that many diseases of a painful character are clearly traceable to the use of hard water, and which are entirely absent in communities who are in the habit of using the soft water of the millstone grit or primitive formations. This aspect of the subject, though worthy of the highest consideration, I leave to those better able to treat it.

The pollution of rivers flowing through agricultural and populous districts is attracting every year more and more the serious attention of the public and the Legislature, and is leading to energetic efforts for the purpose of preventing the contamination to which the rivers are subject, more especially since the adoption of the more complete sewerage and drainage of towns than heretofore existed.

The population within the basin of the river Thames above the points at which the water is withdrawn for the supply of London exceeds 1,000,000 persons, of which 600,000 or 700,000 are congregated in large towns and villages, the drainage of which is either now, or soon will be, poured into the river, unless means are taken for its prevention. It has been conclusively shown that a very small increase in the organic impurities of a river, attributable to animal or vegetable decomposition, renders the water unwholesome, and, notwithstanding the self-purifying quality which running water no doubt possesses, and the efforts which may be made to prevent contamination, the probable condition of our rivers before many years has over is no gratifying speculation.

The supplies to large towns ought to be sought for in those mountain districts where the largest amount of rainfalls, where there is little or no population, where manured lands scarcely exist, and where copious springs are constantly supplying the purest and softest water. It is from such districts that Glasgow and Manchester and most of the large towns in the north of England and Scotland are supplied, and the inestimable benefit which has been conferred on those communities by such supplies can hardly be over-estimated or even appreciated. Such sources, still unappropriated, exist in abundance, but they are distant from London; not too distant, however, to prevent their being economically acquired, although cost in this essential element of healthful existence ought to be matter of secondary consideration.

Large experience in this special branch of engineering for the last 30 years has made me acquainted with almost every available source of supply in the kingdom, and with all the conditions and circumstances which are essential to the successful carrying out of projects of this nature. Some years ago I had occasion to consider a project advocated by the General Board of Health upon the result of surveys by the Hon. Wm. Napier in the Bagshot sands and the greensands of Surrey; and I ascertained from such information as then existed, and from surveys which I personally made, that a moderate supply of very excellent water could be obtained from these districts. It would, however, be altogether insufficient as a complete supply to the City, as a whole and more intimate acquaintance with all the circumstances and difficulties of the country which a residence in it of several years has afforded, has convinced me that, in a succession of such dry years as we have just passed through, the springs would be less than was at the time anticipated, and I could not now recommend the adoption of the scheme which was then advocated.*

No scheme, in my opinion, is worthy of attention which would bring in less than 200,000,000 gallons of water per day, at an elevation which would supply nearly the whole of the metropolitan district by gravitation without pumping.

The nearest district from which this quantity of unexceptionable water can be obtained is that which, lying on the flanks of the mountain ranges of Cader Idris and Plynlimmon, in North Wales, forms the upper basin of the main tributaries of the river Severn. Here the direction of the mountain chains, the heights of their summits, the proximity to the sea, their geographical position, and physical peculiarities, entitle us to expect a very large fall of rain. They are so similar in their general characteristics to the Cumberland and Westmoreland mountains that we should be justified in assuming (in the absence of more precise data), the recorded fall of rain in that part of the country for that which might be expected on the upper drainage of the Severn. A summit ridge or line of watershed, of irregular height and direction, extending from north to south, is crossed and broken by several parallel ranges of mountains extending from south-west to north-east, the intervening valleys on the west side of this irregular summit being quite open to the westerly winds. The valleys on this side, walled in as they are by mountains rising at their peaks to 2,500 and 2,900 feet in height, and so raising their heads above the general level of the rain

* *Vide* Return to an Order of the House of Lords, dated 22nd June 1852, in which, however, a printer's error occurred, by adding a cypher to my estimate, and so making it 12,000,000*l.* instead of 1,200,000*l.*

louds, form, as it were, so many funnels, up which the louds are driven over the low passes at the summit line of ater-shed into the valleys on the east, where, sheltered from ie wind, they discharge the bulk of their watery contents.

Under almost precisely similar circumstances, in the Cumberland lake district, the heads of the valleys on the asterly side of the mountain passes receive an extraordinary amount of rain, amounting in some cases to 150 nches as the rainfall of an average year. The careful bservations of the late Dr. Miller in this district have eterminded not only this almost tropical fall of rain, but lso, in a more conclusive manner than had previously een shown, the gradual increase in the amount as you scend the mountains up to considerable heights. His bservations extended over many years, and have been nore or less corroborated by other meteorologists in those ounties. The observations on the fall of rain in the Welsh nountains are, unfortunately, of a less extensive character, nd have been continued for only a short period, but, as far s they afford the means of comparison, there is every reason o believe that the rain will be found to be as great as it as been ascertained to be in Cumberland. From these bservations we should be justified in assuming the fall of ain in the valleys and upon the hills, from which the Severn derives its supplies, at not less than 70 or 80 inches er annum, on an average of say three successive years of ninimum rainfall.

The rain in the highlands of Scotland on the west coast s probably as great in amount as that which obtains in North Wales and in Cumberland and Westmoreland; but hat which falls upon the drainage ground of Loch Katrine s diminished by the clouds having to pass over several anges of mountains, with deep intervening troughs, efore they reach the hills which surround the basin of his lake. Here, however, the average rain is 78 inches, nd the minimum fall of three successive dry years is 6 inches per annum.

The average annual rainfall on the Penine chain of ills, which forms the backbone of England, as it is ommonly called, separating Lancashire and Cheshire from Yorkshire and Derbyshire and the east and west waterheds of the country, is about 50 inches; the net produce, r that which flows off the ground in dry years, at the Manchester waterworks, which lie in the heart of this istrict being 33 inches per annum.

From all these observations, and from many others which night be brought to bear upon the subject, we should be uite justified in assuming 45 inches as the annual net roduce of two or three successive dry years upon the rainage ground from which I propose to collect water or the supply of London; but in order to be within perectly safe limits I base my calculations on 36 inches only, eing but 10 per cent. more than the observed results at he Manchester waterworks, and probably only half the ross amount of rain.

Having determined the available portion of the annual ainfall which we can safely depend upon, it is a matter of asy computation to determine the area of drainage ground rom which the supplies must be collected; the next imporant considerations being the possible duration of drought, nd the capacity of reservoirs to afford a continuous upply throughout the longest droughts that may occur.

In these mountain districts. where it seldom ceases aining for many days together, storage for 120 days' upply would be ample provision, but I have endeavoured o obtain reservoirs of capacity sufficient to last out 140 or 50 days, without taking into account the produce of the springs and streams during that period, but which would, nevertheless, amount to a considerable quantity.

Among the many districts which present themselves for consideration, two admirable ones have been selected, each apable of supplying, in addition to the natural volume of the streams in dry weather, something more than 100,000,000 gallons of water per day for London, after giving compensation in water to the streams on which reservoirs will have to be constructed, or from which water will be abstracted.

The arrangement for water compensation to the streams and to those interested in the water is proposed to be on the same principle as that on which nearly all such claims have been adjusted in all the great waterworks of the kingdom. By giving a certain definite proportion of the ascertained or assumed available fall of rain, varying in quantity according to the peculiar circumstances of the streams affected, but generally about one-third of the whole amount in the manufacturing districts, where the water is largely utilized, the dry-weather stream, or what may be called the useful working volume, is materially increased to the advantage of those interested, and the reservoirs are filled from the flood waters which run uselessly and often mischievously away, and which form by far the larger portion of the water flowing from a mountain district.

The districts selected are free from metalliferous veins and from other sources of contamination. They are situated on the Upper and Lower Silurian formations, which yield water as pure in quality as that of Loch Katrine, and which affords sites for magnificent reservoirs, which may be constructed with perfect safety and facility, and of sufficient capacity to economize the full annual rainfall I have assumed, and to last out droughts of from 140 to 150 days' duration, both for town supply and river compensation.

One of these districts of 66,000 acres in area is situated a little to the east of the range of mountains, of which Cader Idris and Aran Mowddy are the highest summits, respectively of 2,914 feet and 2,979 feet in height, and forms the drainage ground of the rivers Banw and Vyrnwy, which join the Severn about half-way betwixt Welshpool and Shrewsbury; the other district, of about equal area, is situated immediately to the east of Plynlimmon, 2,500 feet in height, and forms the drainage ground of the upper portion of the river Severn proper. The discharge pipes of the lowest reservoir in each of these districts will be placed at an elevation of about 450 feet above the level of trinity high-water mark.

The water will be conducted by separate aqueducts, of 19 miles and 21½ miles in length respectively, to a point of junction near Marten Mere, a little to the north-east of the town of Montgomery, from whence the joint volume of the water will be conducted by a common aqueduct, crossing the river Severn close to the town of Bridgnorth, and passing near to, or within a few miles of, Stourbridge, Bromsgrove, Henley-in-Arden, Warwick, Banbury, Buckingham, Aylesbury, Tring, Berkhampstead, and Watford, to the high land near Stanmore, where extensive service reservoirs must be constructed, which will be at an elevation of at least 250 feet above Trinity high-water mark. From these reservoirs the water will be delivered to the city at "high pressure" and under the "constant supply" system. The length of the common aqueduct will be 152 miles, and will be capable of conveying 220,000,000 gallons of water per day. The total distance from the lowest reservoir on the Vyrnwy will be 171 miles, and the total distance from the reservoirs on the Severn will be 173½ miles, to which must be added the length of piping from the service reservoirs to London, about 10 miles, making the total distance 183 miles. From the reservoirs to Bridgnorth the aqueduct will be carried through the successive ridges of mountain which it will encounter, principally by tunnelling, in the same manner as the aqueduct from Loch Katrine to Glasgow. At Bridgnorth it will have to cross the Severn by inverted syphon pipes; thence, through a comparatively open country partly by covered aqueduct or tunnel where it is necessary to preserve the water from contamination—partly by open aqueduct where the country is favourable for such construction, and partly by syphon pipes where it crosses the valleys of the rivers Stour, Avon, and other streams. It will avoid all the coal fields near which it passes on its route, and be carried to the north of the saliferous deposits of Droitwich.

The works will be exceedingly simple in their construction, presenting no difficulties of an engineering character. No embankment of a reservoir will be more than 80 feet in height, and they will be placed in situations either where hard impervious clay, or the solid rock of the Silurian formation, afford the means of making perfectly safe and water-tight reservoirs. One of these reservoirs on the river Vyrnwy will, by an embankment of 76 feet in height, form a lake of five miles in length, and will contain 1,089,000,000 cubic feet; another on the river Banw, by an embankment of 80 feet in height, will form a lake of four miles in length, and contain 940,000,000 cubic feet; and a third in the same district, by an embankment of similar height will contain 732,000,000 cubic feet. Amongst the reservoirs on the Severn will be one which, by an embankment of 75 feet in height, will contain 2,230,000,000 cubic feet—this single reservoir being 150 per cent. greater than the available water in Loch Katrine.

The surveys by which these facts were ascertained were made soon after the completion of the Glasgow waterworks, in the autumn of 1860 and in the spring and summer of 1862, and the probable cost of the works has been carefully estimated.

Each branch of the works, down to the junction of their respective aqueducts, will cost in round numbers 1,100,000*l.*; and the main aqueduct from thence to London, including service reservoirs equal to 10 days' supply of 200,000,0000 gallons per day, or 20 days' of half this quantity, will cost in round numbers 6,400,000*l.*—making a total of 8,600,000*l.* These estimates include the cost of connecting the service reservoirs with the main pipes of the existing waterworks and 14 per cent. for contingencies upon the whole estimated cost of works, land, and piping; but the piping provided across the valleys of the main aqueduct is only on a scale of 120,000,000 gallons per day, as it can be added to from time to time as the demand increases. So also it would be unnecessary to construct the reservoirs

on more than one branch of the works in the first instance, by which the outlay of 1,100,000*l.* might be postponed until it was required.

The quality of the water as taken from the streams in dry weather is under 2° of hardness, averaging in fact, according to the analyses of the late Dr. R. D. Thomson, F.R.S., 1·6° only, the average amount of organic impurity being 1·35 grs. per gallon. The water, when collected in reservoirs from floods, will no doubt be softer than this, for the water of Bala Lake, derived from precisely similar geological formation, is but 0°·8 of hardness, with organic impurity of 1·28 out of a total impurity of all kinds of 2·08. The Bala Lake water is nearly identical in quality with the Loch Katrine water, which, from the average of many analyses, contains 2 grs. of impurity to the gallon, of which the organic impurity is less than 1, and the hardness under 1°.

The amount of the estimate need not startle the public, for it is not more in proportion either to the quantity of water to be obtained, or the ability of the inhabitants to pay for it, than has been expended in Glasgow, Manchester, Liverpool, and many other towns, while it is far below the cost incurred by many towns which could be mentioned.

Taking, first, the population as a criterion. The Loch Katrine works cost the people of Glasgow, about 400,000 in number, about 900,000*l.* for an immediate supply of something more than 20,000,000 gallons per day, with provision in most respects for 50,000,000; the Manchester waterworks, for a supply (if the works were quite completed) of about 25,000,000 gallons a day to 600,000 persons, have or will cost 850,000*l.*; the Rivington works, for the supply of Liverpool, equal to only 12,000,000 gallons a day to a population of perhaps 500,000, have cost about 900,000*l.* Of these three great enterprises Glasgow is much the cheapest, as, by a further outlay of about 200,000*l.*, or a total of 1,100,000*l.*, it can secure a supply of 50,000,000 gallons per day.

These figures summarized show that the cost of new works for procuring additional supplies of water has been: in Liverpool about 75,000*l.* for each million gallons per day, in Manchester 34,000*l.* for a like quantity, in Glasgow about 45,000*l.* for their first instalment from Loch Katrine, and 22,000*l.* per million when their full quantity is obtained.

The cost to London, estimated in this way, though smaller than in Liverpool, would exceed that of Glasgow and Manchester, for it would be 71,000*l.* per million for the first instalment of 120,000,000 gallons, and 49,300*l.* per million when the full quantity was obtained; but, as compared with many other places, London would contrast more favourably.

The cost of new works, however, only forms a portion of the gross cost of the supply of any of these places. The price paid for the previously existing companies has in each case to be added; and including this, and looking merely to the population, Glasgow and Manchester have obtained their water cheaper than London could do by any scheme to be proposed. The gross cost, including the purchase of previously existing rights, in each of these places and in Liverpool, has been, or will be, as follows:—

	Gallons per Day.	Cost.	Per Million Gallons.
		£	£
In Liverpool, for . .	16,500,000	1,900,000	or 115,115
In Glasgow, including the supply from the Gorbals waterworks and first instalment from Loch Katrine	27,000,000	1,600,000	,, 59,260
Ditto, when full supply from Loch Katrine is obtained	53,500,000	1,800,000	,, 33,645
In Manchester . . .	25,000,000	1,500,000	,, 60,000

In Liverpool about one-third of the water supplied has still to be pumped from the old wells in the new red sandstone, the annual cost of which should be capitalized, and the amount added to the gross cost of the works, before it can be compared with Manchester or Glasgow. If this were done it would raise the cost of supplying water there to 1,990,000*l.*, or 120,606*l.* per million gallons per day.

In London the gross cost, after capitalizing the present dividends and interest of the existing companies, if they are to be purchased, viz., 450,000*l.* per annum, at 25 years' purchase, will be 19,850,000*l.* for the first instalment of 120,000,000 gallons per day (exclusive of any of the New River supplies which may still be retained), or 165,416*l.* per million; when the full quantity from North Wales is introduced, viz., 220,000,000 gallons per day, the total cost will be 22,100,000*l.*, or 100,454*l.* per million gallons per day.

It would not be fair, however, to consider population only as a test of ability to pay for water. A fairer criterion is the assessable value of the respective places; and in this view, if water is to be paid for according to the value of the property to be supplied, London stands on nearly equal terms with any of the places named.

The gross assessable value, both in Glasgow and Manchester, upon which compulsory rates can be levied is about 1,200,000*l.*, of which, in both cases, almost exactly half, or about 600,000*l.*, is due in respect of dwelling-houses. The gross assessable value of London within the metropolitan district is nearly 15,000,000*l.* per annum, of which at least 10,000,000*l.* must be on dwelling-houses, in respect of which alone rates for domestic supply would be levied. If, therefore, you look at the gross assessable value London could bear an expenditure twelve times as great as that incurred by Manchester and Glasgow, or, on the average cost to the two places, nearly 19,000,000*l.* sterling and if you measure it by the assessment on dwelling-houses, it could bear an expenditure about sixteen times that borne by the two enterprising cities of the North, or a gross outlay of about 25,000,000*l.* sterling.

Fortunately for the citizens of London, they need not be afraid of having to provide for such an outlay, if the system which has been adopted in Glasgow and Manchester, and which has been found to work in every way so advantageously for all parties, be adopted in London.

In each of these cities the waterworks are the property of the corporation, and, therefore, of the inhabitants themselves. Manchester has the power to levy within its municipal bounds two unlimited compulsory rates; one called the *public* rate, levied in consideration of the protection against fire which "constant supply" and "high pressure" necessarily confer, and in consideration also of the great advantage which all property is supposed to derive from a full supply of water; and the other a *domestic* rate in respect of the water supplied for domestic purposes. In Glasgow the corporation have the power of levying a public rate not exceeding 1*d.* in the pound, an unlimited domestic rate on the city north of the Clyde, and a rate of 1*s.* in the pound on dwellings in that part of the city which lies on the south of the Clyde. These rates in all cases, in both cities, are compulsory rates leviable upon all parties, whether they take water or not. They are, moreover, leviable upon the actual rental of the property, and not upon the mere assessable value, which is always below the rent. Outside the city boundaries, and within the city for trading purposes, both corporations stand in the position of ordinary trading companies, selling the water to those who will take it at certain limited rates for the supply of dwellings, and on terms to be agreed upon for the water taken for trade. These extraneous sources of income form a very considerable portion of the water rental of both the cities, no less an amount than 56,324*l.* having been received last year in Manchester, and 35,277*l.* in Glasgow being equal to 145 and 65 per cent. respectively on the gross revenue derived from the domestic and public water rates.

The rates actually levied within the compulsory area at present are—in Manchester, 9*d.* in the pound for the domestic, and 3*d.* for the public rate; and in Glasgow, 1*s.* for the domestic, and 1*d.* for the public rate. Shortly after the completion of the Loch Katrine works, when the full amount of interest on capital came to be paid, and before the expansion of the supply for trading purposes had had time to develope, the domestic rate in Glasgow rose to 1*s.* 4*d.* in the pound on the north side of the river, which in addition to the public rate, was cheerfully and thankfully paid. For some years the rates in Manchester were eased to the inhabitants by a moiety of the gas profits, which belonged to the township of Manchester, being applied in part payment of the interest on the cost and the annual expenses of the waterworks. During this period the domestic and public rates were respectively 6*d.* and 2*d.* in the pound. Now, however, and for several years past, no assistance has been derived from this source, and rates of 9*d.* and 3*d.* are, with the trade income, sufficient to meet all the expenses of the undertaking.

In Liverpool, where the corporation also have the power of levying compulsory rates, the domestic rate is unlimited but the public rate is restricted to 6*d.* in the pound upon all property. The full amount of this public rate is actually levied, being (where the supply is for domestic purposes) in addition to a present domestic rate of 4½*d.* in the pound. The extraneous income, from the sale of water for trade, shipping, &c., for the year ending December 31st, 1864, was 39,508*l.*

In these cases, as in all others where corporations have been permitted to take the supply of water into their own hands, they have been obliged to purchase previously existing water companies, whose property was valued and paid for upon a fair estimate of the profit they could legitimately make; this system of purchase being that almost universally adopted in all the various cases where, of late years, the waterworks of companies have passed into the hands of corporations.

Now London has but to follow the example of the places named (and they are not the only places which might be held up as examples, although, perhaps, Manchester and

lasgow are the two most prominent cases of success), id it can obtain its water quite as good in quality and ite as cheap in price.

It is fortunate that the experiment of uniting the whole etropolis into one district, for drainage and other purposes hich affect its material prosperity, has already been tried id found successful in the case of the Metropolitan Board ' Works; and it would be a simple and no doubt an fective arrangement to let that, or a similar Board, stand . the place of the corporation in other towns, and be rmed into a water commission or corporation for the anagement of the whole water supply of the metropolis, ith power to levy, as in Manchester, Glasgow, Liverpool, id other places, compulsory rates for the payment of the terest on the outlay and the necessary working expenses.

There can be little doubt but that upon the security of ompulsory rates leviable upon all the property in the etropolis, the various water companies would be willing sell their undertakings, on condition of receiving the same ividends which they have been in the habit of receiving, he board or corporation taking upon themselves all their lia- ilities, and the payment of the interest on money borrowed.

According to the annual returns made by the several ater companies to the town clerk of the City of London, he gross amount of water rents of all kinds now received y the seven largest companies which supply the metropolis 702,059*l.* per annum; their working expenses, of which very large portion consists of the cost of pumping water, re 275,547*l.*, leaving a balance for the payment of interest n money borrowed and dividends to the shareholders of 27,512*l.* A portion of this sum is made up of the rental eceived from houses, chief rents, and other property; and hen the pumping establishments can be dispensed with on he introduction of water from Wales, a large amount of ery valuable property would be set at liberty, and might e disposed of to great advantage. The eighth company, iz. the Kent waterworks, no doubt from oversight, has ever made the returns required by Act of Parliament, and ts receipts and expenditure cannot therefore be ascertained y reference to public documents.

By the concentration of management which would result rom the amalgamation of all the various companies into one reat undertaking, a considerable annual saving would be ffected, and the whole cost of filtering, and nearly the hole cost of pumping water, which are estimated to cost bout 75,000*l.* a year, would be saved. There would, even fter the completion of the projected scheme, be some high oints and distant places to which the water would have to e supplied by the aid of steam power and pumping, but he quantity thus to be supplied would be small in propor- ion to the great bulk required by the remainder of the metropolis, and would form no very serious addition to the annual expenses.

I referred in the beginning of this paper to the rapid increase in the population of London and its suburbs, and now it is necessary to refer to the no less rapid, and, indeed, astonishing increase in the value of property. In 1862 the assessable value of property within the metropolitan district was 12,514,053*l.* Upon a reassessment this year (1865) the annual value is 14,524,797*l.*, and taking the progress of the past as an indication of what may be fairly assumed as the progress of the future, the assessable value of property within the metropolitan district may be expected to be 20,000,000*l.* sterling by the time all the works could be completed for bringing in a supply from North Wales, a period which may be estimated at, perhaps, seven years from the present time. Not, however, to overrate the means from which the annual revenue must be derived, I will take it at 18,000,000*l.* only, and, in the absence of correct information, I will assume the value of dwellings at two-thirds of this sum, or 12,000,000*l.* per annum.

From the figures I have thus briefly introduced, and adopting the principle I have advocated of a compulsory rate upon all parties within the metropolitan district, it is easy to calculate how far the scheme I have proposed will work out in a financial point of view. Before, however, stating these results, I may urge one aspect of the subject which, if favourably viewed by those to whom it must be addressed, would lighten the burden to be borne by the community.

The question is to some extent an imperial one, and it would be no unreasonable thing if such assistance were solicited from Government as would enable the board to borrow their money at the lowest possible rate at which money could be afforded by the State. The metropolis is not merely the home of the citizens of London—it is the residence of the Crown and the Court, the seat of the Government, the centre of parliamentary legislation, and the place in which the great bulk of the legal business of the country is transacted. Annually, for a certain portion of the year, all the wealth and fashion of the kingdom congregate within its limits, and it is, indeed, in every relation of life and business, so identified with the interests and well-being of the whole kingdom, that the public generally might well be called upon to contribute to a measure of such importance, by permitting the State to lend money for the undertaking, for a limited period, at three per cent. interest per annum. Except, however, for the relief of those who are the constant residents of London, and who form the great bulk of its population—the smaller tradesmen and shopkeepers, and the working classes—it is hardly necessary to look for such assistance.

Assuming, for purposes of calculation, that the money to be borrowed may be obtained at four per cent. interest, and cannot be obtained at less, and that the companies will be satisfied with the payment of their present dividends, secured upon the compulsory rates, the annual sum required to meet all items of expenditure will be as follows:—

The total cost of the works on a scale, so far as the aqueduct is concerned, of 220,000,000 gallons per day, and reservoirs and pipes for the supply of 120,000,000 gallons, will be 7,460,000*l.* To this sum must be added the cost of surveys, parliamentary expenses, interest upon money during the construction of the work, the cost of superintendence, legal expenses, and such like, and these I estimate at 1,140,000*l.* by the time the works are completed, making a total of -	£8,600,000
The interest upon this, at four per cent., is	£344,000
Add cost of management and working expenses, say - - - -	150,000
Payment of dividends to existing companies, and interest on their borrowed money	450,000
Total annual expenditure	£944,000

To meet these charges there would be received—	
Probable annual value of surplus property of companies which may be disposed of	£50,000
Sales of water for trading purposes, and to suburban districts, and places on the line of aqueduct, probably - -	250,000
Compulsory rate for domestic supplies, at 10*d.* in the £, on 12,000,000*l.* - -	500,000
Compulsory public rate, at 2*d.* in the £, on 18,000,000*l.* - - - -	150,000
Total annual income	£950,000

The above is the worst view that can be taken of the financial position. Every succeeding year after the completion of the works the area of taxation and the means of raising revenue will be increased by the extension of the metropolis, while the annual expenses will remain nearly stationary, until the full quantity of water which the aqueduct will bring is exhausted. When this time approaches other contiguous mountain districts must be laid under contribution and a new aqueduct constructed. Twenty-five or 30 years will probably elapse before this occasion arises, even if none of the present supplies, such as those of the New River Company, which can be supplied by gravitation, are looked to as auxiliary means for meeting many public and trade demands where superior quality of water is not essential.

Possibly some of the items of probable revenue in the estimate I have made may be regarded with doubt, such as that to be derived from the sale of water for trade purposes and suburban districts. It is, however, considerably within the result obtained in Glasgow, in Manchester, and in Liverpool, and may, therefore, be fairly expected to be realized; but should it fall short of the sum estimated, and should the money have to be raised at four per cent. interest, as I have assumed, the compulsory rates must be correspondingly increased by perhaps 1*d.*, or at most 2*d.*, in the pound, when, even then, they would be below those which have been paid by Glasgow, and much below those paid in many other places. A reduction of one per cent. interest on the capital to be raised for new works would make an annual saving of 85,000*l.*, and if, by the aid or favour of Government, a further sum could be obtained at this amount of interest for the purchase of what would become water companies' annuities, at 25 years' purchase, there would be a further saving of 116,000*l.* per annum, making a gross annual saving of 201,000*l.*, being equal to a reduction of 4*d.* in the pound on the domestic rate. If this can be accomplished the metropolis will acquire not only an unlimited supply of water, delivered in the most perfect manner, and unsurpassed in purity and softness, but it will obtain it at no greater annual cost per head than is paid for a similar inestimable benefit in Glasgow and Manchester.

JOHN FREDERIC BATEMAN.

16, Great George Street, Westminster,
November 1865.

TABLES.

Table A.—Metropolis Water Supply.

Estimated cost of new supply from North Wales to carry out one branch of the scheme, either that for bringing wate from the river Severn or from the rivers Vyrnwy and Banw, and to construct the aqueduct from Marten Mere t London, capable of conveying 220,000,000 gallons per day:—

	£
Reservoirs and works on the rivers Vyrnwy and Banw, or on the upper sources of the Severn, and the construction of the aqueduct from the reservoirs to Marten Mere, capable of conveying 130,000,000 gallons per day, including land and contingencies	1,100,000
Main aqueduct from Marten Mere to London, capable of conveying 220,000,000 gallons per day, including land and contingencies, and including also the piping from the service reservoirs to London	5,860,000
Service reservoirs near London, including land and contingencies, and cost of connecting new piping with the existing systems	500,000
	7,460,000
Interest on outlay during construction of works, and general expenses, &c., &c.	1,140,000
Total cost for the first supply of 130,000,000 gallons per day	£8,600,000

Subsequent outlay for completing the whole scheme for 220,000,000 gallons per day:—

Cost of first 130,000,000 gallons per day	8,600,000
Reservoirs and works on the second branch of the scheme to Marten Mere	1,100,000
Additional syphons on main aqueduct between Marten Mere and London	550,000
Outlay for additional piping in the metropolitan district, service reservoirs, interest on outlay during construction of works, and general expenses	600,000
	£10,850,000

TABLE B.—General Particulars of the Drainage Areas, Estimated Supply of Water, and Reservoirs

DISTRICT.	Drainage Ground.	Assumed available Rain-fall per Ann.	Total Average Quantity per Day.	Assumed Compensation to Rivers, One-fourth.	Remains for City per Day.	Particulars of Reser		
						Height of Embank-ment.	Area of Surface of Reservoir.	C

	1863	26·88	3·28		
	1865	27·72	1·61	17·71	5·53

* The permanent hardness in the analyses for 1856 is "after five minutes' boiling," that in the analyses for 1865 "after one hour's boiling."

The analyses for April 1856 are obtained from the report of Messrs. Hofmann and Blyth to the Hon. W. Cowper. The other analyses are obtained from the published returns of the Registrar-General; those for 1862 and 1863 being by the late Dr. R. D. Thomson, and those for 1865 by Dr. Frankland, F.R.S.

In reference to the analyses for the year 1865, in the preceding table, I have the following note from Dr. Frankland, dated Nov. 11th, 1865:—

"The composition of the waters supplied by the London companies is liable to considerable fluctuation, and you have selected a month peculiarly favourable for them. The results of analyses made here" (Royal College of Chemistry) "since February last, go to show that long-continued drought improves the quality of the waters, whilst rain has the opposite effect. Thus the dry spring and summer have, up to October, rendered these waters exceptionally good; and the results of analyses of waters collected this month (November), so far as they have been ascertained up to the present moment, show considerable higher numbers.

"In order that you may judge of this influence upon the quality of the waters, I append the proportions of solid contents and *volatile* or, as it is sometimes termed, *organic* impurity in the Lambeth Company's water from February to October of the present year" (1865).

LAMBETH COMPANY'S WATER.

1865.	Total solid Residue in 100,000 parts.	Volatile Matter in 100,000 parts.	Equivalent Results in Grains per Gallon, for comparison with the preceding Table.	
			Total Impurity.	Organic Impurity.
February	31·36	2·70	21·95	1·89
March	29·10	2·00	20·37	1·40
April	25·69	1·14	17·98	·798
May	27·60	1·95	19·32	1·36
June	25·34	1·55	17·74	1·08
July	23·15	·97	16·20	·68
August	25·18	1·12	17·63	·78
September	25·35	1·45	17·74	1·01
October	25·26	1·34	17·68	·94

TABLE E.—TABLE showing the AVERAGE RAINFALL in the CUMBERLAND and WESTMORELAND LAKE DISTRICT, from Observations made by the late Dr. MILLER, F.R.S., from 1844 to 1853.

Highest summits of the district, about 3,000 feet.
Lowest level, about 200 feet.

Place of Observation.	Elevation above the Sea.	No. of Years' Observations.	Mean Rainfall.
	Feet.	Years.	Inches.
Keswick	258	10	59·6
Loweswater	336	10	67·29
Crummock Lake	260	10	84·1
Gatesgarth	290	9	114·7
Eskdale Head	—	7	77·9
Wastdale Head	247	10	101·4
Selside	736	5	73·5
The Howe, Troutbeck	503	10	79·3
Ambleside	190	6	79·6
Seathwaite	—	9	140·5
Stonethwaite	340	7	111·4
Mean rainfall per annum of the district			89·93

TABLE showing RELATIVE RAINFALL at Places near the Sea, to the West of, and immediately adjacent to, the Mountains; and the RAINFALL in the LAKE DISTRICT generally, as above.

Place of Observation.	Elevation above the Sea.	No. of Years' Observations	Mean Rainfall.	Average Rainfall at places near the Sea.	Average Rainfall in the Mountain District adjacent.
	Feet.	Years.	Inches.	Inches.	Inches.
Whitehaven	90	10	43·5	46·75	89·93
The Flosh	—	10	50·0		

TABLE showing the RAINFALL in NORTH WALES, from SEA LEVEL to the MOUNTAIN DISTRICT adjacent, being the Returns for Six Months, ending August 1865.

PORT MADOC. Elevation, 20 feet above Sea.	MAEN-HOROG, CAEN-Y-COED. Elevation, 15 feet above Sea.	FESTINIOG. Elevation, 600 feet above Sea.	RHIWBRYFDIR. Elevation, 1,200 feet above Sea.
17·85 ins.	20·34 ins.	27·77 ins.	33·31 ins.

TABLE of the RAINFALL at two Places in each of the CUMBERLAND and WELSH DISTRICTS, showing the Relative fall of Rain at or near the Level of the Sea, and at Places nearer to the Mountains.

	CUMBERLAND LAKE DISTRICT.		WELSH DISTRICT.	
	Whitehaven.	Loweswater.	Port Madoc.	Festiniog.
Elevation above the sea	90 feet	336 feet	20 feet	60 feet
Rainfall	43·53 ins.	67·29 ins.	45·75 ins.	74·80 ins.

The rainfall of the Cumberland Lake district is the mean annual rainfall of 10 years.

In the Welsh district it is for 15 months, from May 1864 to August 1865 inclusive, omitting January 1865, for which month no return has been obtained. This return is worthy of notice, as being the record of a remarkably dry period.

The returns of the rainfall in Wales in the preceding tables are from the observations of Captain Mathew, of Wern, near Port Madoc.

TABLE F.—TABLE showing the AVERAGE RAINFALL in the LOCH KATRINE DISTRICT of the GLASGOW CORPORATION WATERWORKS.

Highest summit within area of drainage ground, Ben Venue, 2,800 feet. Lowest level about 300 feet.

Place of Observation.	Elevation above the Sea.	Number of Years' Observations.	Mean Rainfall.
VALLEY GAUGES—	Feet.	Years.	Inches.
Loch Venechar	275	4	64·7

APPENDIX F.

(REPRINT OF PAMPHLET.)

On the FUTURE WATER SUPPLY of LONDON.—By GEORGE WILLOUGHBY HEMANS, C.E., and RICHARD HASSARD, C.E.

THE ideas on which the following project is based have been for a long time under consideration, and the descriptive particulars were actually preparing for circulation when the public were presented with the views on this subject of a very eminent gentleman, Mr. Bateman, C.E., in the form of a pamphlet, ably written and extensively circulated, and which has already attracted a large amount of remark and approval.

It is felt, therefore, that these suggestions appear now somewhat at a disadvantage, particularly as the sources of water supply recommended would seem at first sight to demand works, in length and extent, of greater and more startling magnitude than even the already sufficiently bold project of Mr. Bateman, for bringing water to London from the Welsh hills at a distance of 183 miles. The sources herein recommended lie at a distance of 240 miles from London, but, notwithstanding this increase of distance, we believe that when the subject is fully investigated it will appear that our project—although involving an apparently larger outlay in the first instance—will, from the absolute certainty of the rainfall, the extraordinary purity of the water, the facilities afforded by the existing lakes for the construction of the immense reservoirs, and from the revenue which may fairly be expected from the sale of water in the districts traversed by the aqueduct, be found the best and cheapest which has yet been proposed, and that ultimate economy will arise from its selection.

The future water supply of London, from its magnitude and importance, from the sanitary considerations involved in its successful elucidation, and having in view the enormous and rapidly increasing population which will afterwards be dependent upon it for one of the chief necessaries of life, is a question without parallel in the history of engineering, in ancient or modern times.

Of the existing water supply little need be said; that it is imperfect and unsatisfactory, both on account of quality of water, the intermittent nature of the supply, and rate of charge, is admitted on all hands; whilst, from the peculiar circumstances of the case, it is scarcely possible for the water companies to afford a supply much larger in quantity, or better in quality, than that at present furnished; they have done their best to carry out the obligations imposed on them by the Acts of 1852, and have expended large sums in their attempts to do so; the limit they can attain has, however, been nearly reached, and if the metropolis is to have a supply of pure water, such as is now enjoyed by many of the provincial cities and large manufacturing towns in the kingdom, it is full time that measures should be taken to investigate the question, and secure a suitable district from which to attain it, their being very few available localities now unappropriated, or which will not, owing to the growing necessities of this populous country, shortly be appropriated, for the supply of other towns and districts.

The population of London and its suburbs has increased of late years in such an extraordinary ratio—with the probability of at least this rate of increase being maintained—as to render it absolutely essential that any scheme now put forward should be designed so as to admit of a quantity of water, at least double the existing consumption, being brought to the metropolis, from time to time, as the requirements of the district demand additional supplies.

The population of the metropolis and suburbs may be taken at 3,000,000, and the quantity of water now actually supplied by the different companies at nearly 100,000,000 gallons daily.

Of this a very large proportion (about one-half) is extracted from the Thames, above tidal influence, as required by the Acts of 1852, and such a serious diminution of the volume of water in the river flowing onwards to London has of late attracted great public notice, to which it is not necessary at present further to advert.

The following extracts from the Registrar General's monthly reports, as published in the "Times," will show the qualities of the waters so obtained, as well as those of the waters of the other sources from which the metropolis is now supplied :—

"ANALYSIS of the METROPOLITAN WATER in December 1865, by Professor FRANKLAND, F.R.S., of the Royal College of Chemistry :—

New River -	30·02	0·54	·0396	7·0	14·1	21·1
East London -	33·90	1·56	·1274	7·2	15·0	22·2
South Essex -	38·10	0·86	·0112	5·8	19·0	24·8

"The table may be read thus :—100,000 lb. of the Chelsea water contained 28·00 lb. of solid matter, of which 15·2 lb. of organic and other matters were driven off by incineration. ·097 lb. of oxygen were required to destroy organic matter in the said quantity of Chelsea water. Of the solid matter, 16·1 lb. are carbonate of lime or its equivalent; of which 9·1 lb. are got rid of by boiling, and 7·0 lb. remain.

"With the exception of the water supplied by the Kent and South Essex Companies, the waters again exhibit this month a marked increase in the total amount of solid impurity as compared with last month; this applies also to the water supplied by the Lambeth Company, which was the only one which in October showed no increase of residue over the preceding month. On the other hand the organic and other volatile matter has (with the exception of the water supplied by the Grand Junction Company) decreased; while the amount of oxygen required for oxidation of the organic matter is in most cases less than in November.

"The waters of the Chelsea, Lambeth, Southwark, Grand Junction, and East London Companies were turbid when drawn from the companies' mains.

"The second column of this table contains the amount of solid matter left on evaporation and desiccation at 120 deg. C.—130 deg. C. (248 deg. F.—266 deg. F.)

"The results are recorded in 100,000 parts. By moving the decimal point one place to the right, the above figures express in milligrams the quantities contained in one kilogram of the several waters.

* The degree of hardness hitherto employed by chemists is that first proposed by Dr. T. Clark—viz., one grain of carbonate of lime, or its equivalent, in one imperial gallon of water, or one part in 70,000. The degrees of hardness used in the above table are readily converted into Clark's degrees by multiplying by 7, and then moving the decimal point one place to the left.

"NOTE.—The quantities of water here given include the supply for manufactures and for various purposes other than domestic consumption. The table may be read thus:—The Chelsea Water Company supplied 26,430 houses, and an average daily quantity of 7,658,800 gallons in the month of January; 100,000 lb. of the Chelsea water in February contained 31·14 lb. of solid matter, of which 2·59 lb. of organic and other volatile matters were driven off by incineration. ·0912 lb. of oxygen was required to destroy organic matter in the said quantity of Chelsea water. 21·1 lb. are carbonate of lime or its equivalent. The fourth column of this table contains the amount of solid matter left on evaporation and desiccation at 120 deg. C.—130 C. (248 F.—266 F.) The results are recorded in 100,000 parts. By moving the decimal point one place to the right the above figures express in milligrams the quantity contained in one kilogram of the several waters.

"In comparison with the month of January the majority of the waters exhibit an increase in the total amount of solid impurity: the West Middlesex, New River, and East London Companies' waters form the only exceptions to this rule. The amount of organic and other volatile matter is also greater in all the waters, except those of the Grand Junction, Lambeth, East London, and South Essex Companies. Lastly, a larger quantity of oxygen is required for the oxidation of the organic matter than in the preceding month; the Chelsea, Grand Junction, South Essex, and Lambeth Companies' waters only being excepted.

"The waters of the Chelsea, Southwark, Lambeth, New River, and East London Companies were turbid when drawn from the Companies' mains."

The analysis for January was not published, but it will be evident from the remarks in that for February, that the water must have been of a quality similar to that of the preceding and following months.

It will be apparent also, from the above statements, that as regards six of the water companies, for some periods of the year at all events, private filtration would be necessary (it is in fact extensively practised) to ensure to the consumers a bright and potable water.

Taking for example the month of February, it would appear that out of a total daily average supply of 88,588,211 gallons no less than 67,326,000 gallons, or more than three-fourths of the whole, were delivered to the consumers in a turbid state.

The attributes of the future supply must be quantity, purity, and softness, with distribution at high pressure, on the constant system.

It would not be prudent, therefore, to provide for an eventual supply of less than 250,000,000 gallons daily, that is, 200,000,000 gallons for the metropolitan districts proper, and 50,000,000* gallons for sale to districts traversed by the aqueduct *in transitú* into London.

Experience has hitherto shown that the largest waterworks are in the end the cheapest, and those which furnish the largest quantity, and combine a supply for trading and manufacturing purposes with that for domestic and private consumption, invariably supply water at the lowest rate, to the ordinary consumer—that is, to the public at large.

This project is therefore put forward for the supply, not only of London, but where necessary, of the vast populat lying between the districts from which it is proposed obtain the water and the metropolis itself; and in th intermediate districts lie the populous and thriving tow of Lancashire, of the Potteries, and of the Midland Count

By such an arrangement it is obvious that the cost to parties will be materially lessened.

To obtain this necessarily great quantity of water, requisite purity and softness, we must seek a district considerable area, free from peat and contamination of ev kind, where the rainfall is large, and ascertained beyc doubt by a long series of observations, and where facilit exist for storing up the surplus waters of wet seasons, such altitudes as to permit of the supply being drawn and conveyed to London by gravitation, and of bei delivered there at about 220 feet above high water; usi in all cases where practicable the existing covered serv reservoirs, and failing these, covered service reservoirs to constructed in such localities as may be found on investig tion most advantageous for utilizing the present pipes a works of distribution.

This altitude of about 220 feet for distribution wou be most convenient and suitable for the entire of t metropolitan districts, would ensure an ample pressure ordinary domestic supply and in case of fire, and wou avoid the abandonment and destruction of the existi appliances of distribution, which would be entailed by t use of a much higher pressure, and by the adoption of different system of service; in fact the metropolis is large as to preclude its being dealt with otherwise than districts, excepting by the abandonment of a great porti of the present works and pipes, involving an obnoxious a undesirable expenditure.

There are, it is true, some elevated suburban districts f the service of which it would still be necessary to raise wat by pumping, but these could not, under any circumstance be included in a project for the supply of the metropolita districts by gravitation, and their area is comparatively small that it is scarcely necessary to notice them in the co sideration of this important subject.

Those well-known mountain ranges of the counties Westmoreland and Cumberland, draining into the river Lowther, Eamont, and Greta, and adjoining the lakes Haweswater, Ullswater, and Thirlmere, possess all th attributes of a locality from which an enormous amount the purest possible water may be obtained; and the existin lakes can easily and at small expense be adapted to for immense reservoirs for its conservancy and storage, at con venient altitudes for the water to be drawn off and conveye by gravitation to London.

By this process of conservancy the expense and incon venience of constructing such a number of wholly artificia reservoirs as would otherwise be necessary for the storag of the immense requisite quantity of water will be obviated

The area from which water is herein proposed to be col lected extends over 177 square miles, the altitudes varying from 500 to 3,200 feet above the sea. These, however, ar the extremes, the mean altitude will probably be 1,300 o 1,400 feet above the sea level.

The entire district is bare hill pasture and rock of th primitive formations, and excepting a small area in th vicinity of Ullswater, which can easily be excluded from th scheme, is free from mineral workings or other source of contamination, and the waters are of remarkable purity and softness, as the following analyses by and letter from Professor Way will show:

GRAINS PER IMPERIAL GALLON.

	River Lowther.	Haweswater Lake.	Ullswater Lake.	Thirlmere Lake.
Lime - - - - -	1·54	0·50	0·81	0·42
Magnesia - - - -	0·50	0·18	0·20	0·14
Soda - - - - -	0·80	0·71	0·51	0·46
Chlorides of Sodium & Potassium	0·48	0·40	0·69	0·77
Oxide of Iron, Silica, &c. -	0·50	0·25	0·20	0·05
Sulphuric Acid - - -	0·51	0·51	0·37	0·44
Carbonic Acid - - - -	2·05	0·82	1·03	0·56
Organic Matter - - -	0·62	0·62	0·35	0·77
Total Impurity - - -	7·00	3·99	4·16	3·61
Hardness before boiling - -	5·2°	2·0°	2·1°	1·5°
Hardness after boiling - -	4·4°	1·8°	2·1°	1·5°

* A small addition to the size and cost of the aqueduct would enable the provincial supply to be increased at any future time to 100,000,000 gallons daily.

These substances are probably combined as follows:—

GRAINS PER IMPERIAL GALLON.

	River Lowther.	Hawes-water Lake.	Ulls-water Lake.	Thirl-mere Lake.
Carbonate of Lime	2·75	0·90	1·45	0·75
Carbonate of Magnesia	1·05	0·36	0·42	0·29
Carbonate of Soda	0·70	0·56	0·40	0·20

Oxide of Iron, Silica, &c.	0·50	0·25	0·20	0·05
Organic Matter	0·62	0·62	0·35	0·77
Total Solid Matter	7·00	3·99	4·16	3·61

106, Leadenhall Street, E.C., March 21, 1866.

DEAR SIR,

I ENCLOSE the analyses of the waters of the river Lowther and of the three lakes, Haweswater, Ullswater, and Thirlmere.

As might have been expected, none of them shew more than a small proportion of solid matter per gallon; the river Lowther is the least praiseworthy on this account, though even that sample contains only 7 grains of total impurity per gallon.

The proportion of organic matter in all the samples is small; the water of the river Lowther is, however, slightly coloured, no doubt from peat.

The waters of the three lakes are as soft as any natural waters can be; the water of the river Lowther does not equal the others in this respect, but, as compared to the usual towns' supplies, would be considered a soft water.

On the whole, I have no hesitation in saying, that any one of these waters, or a mixture of them, would be admirably suited for the domestic supply of town populations, whether large or small.

I am, dear sir,

Yours truly,

G. W. Hemans, Esq., C.E. J. THOMAS WAY.

These results, although so favourable, exhibit the waters in their worst aspect and condition; the samples for anlaysis having been taken in January last, immediately after long continued and heavy rains, and include the drainage from the small mineral district, which is intended to be excluded from the scheme.

On the subject of the sufficiency of the rainfall no difference of opinion, happily, can arise.

The observations of the late Dr. Miller from 1847 to 1853 inclusive, as published in "Beardmore's Manual of Hydrology," give for the district and neighbourhood an average mean annual rainfall for that period of 100·56 inches, as will be apparent from the following table (No. 1).

It is a matter much to be regretted that the records of rainfall for this hill district, so carefully compiled up to 1853, should have been for the most part discontinued after Dr. Miller's death, as the years 1854 to 1859 inclusive were dry years, the mean annual rainfall of the 10 years 1850 to 1859, as given by Mr. G. J. Symons in his "British Rainfall" for 1863, as registered at the Seathwaite gauge, being 126·98 inches, as against 138·52 inches, the mean annual rainfall of the seven years ending 1853, and the mean annual rainfall at the Keswick gauge being 55·01 inches as against 60·82 inches for the same period of time, being in the first case ·92 and in the second ·90 per cent. of the mean annual rainfall of the seven years ending with 1853, which was a very dry year.

The years 1864 and 1865 were also dry years, the latter indeed, in the north-western counties, being one of extreme drought; the mean rainfall in the lake district for that year having been only 80·38 inches, or about 80 per cent. of the mean annual rainfall (100·56 inches) of the district for the seven years ending with 1853. (See Table No. 3.)

1864	73·20	86·78	7·21	119·52	108·73	—	134·67	100·76	52·68	—	74·40	74·09	75·74	74·63	61·49	35·08	-
1865	49·12	75·73	68·27	103·84	99·85	149·07	117·49	84·13	49·18	—	65·78	65·80	64·05	71·00	61·99	—	-

Mean rainfall of the district in the year 1864 = 81·99 inches.
Ditto - - - - - 1865 = 80·38 „

These last are rather lower than the true mean rainfall, owing to there not having been a gauge at the Stye in the year 1864, and owing to the Scafell gauge being rendered useless from snow during the greatest portion of the first three months of 1865.

In estimating for the supply of London and the intermediate towns the water producing capabilities of the district, we take it, to avoid question, at somewhat less than its minimum, viz., at 80 inches.

In a precipitous hill and rocky district, such as this, the loss from evaporation and absorption will be small, probably not more than 12 inches; we take it, however, at 14 inches, leaving 66 inches as the minimum depth of available rain during a continuous period of dry seasons.

This would be equivalent to a supply of 464,719,562 gallons daily throughout the year, and is a quantity much larger than required, or indeed than could be conveniently dealt with.

It is proposed therefore to limit the supply from this district to 250,000,000 gallons daily, and to give as compensation a quantity nearly equivalent to one-third of the abstracted rain, viz., 450,000 gallons daily for each square mile of drainage area.

By such an arrangement the floods now running to waste would be to a great extent controlled, and the dry weather yield of the district probably doubled in volume.

It will be evident that the district is capable of supplying a far larger quantity of water than that which it is proposed to take from it; in fact, the main cost of the project would be incurred, not in collecting and impounding the water, but in conveying it from its native district to the places of consumption.

The descriptive particulars of the project are as follows, and will best be understood by reference to the accompanying map:—

The districts from which water is proposed to be taken, with two small exceptions, lie on the northern slopes of the range of hills towering over Grasmere, Windermere, and Kendal, and draining into the rivers Lowther and Greta, and into the lakes of Haweswater, Ullswater, and Thirlmere.

On the eastern side of the collecting ground the works would commence on the river Lowther at Cooper's Green, in Sleddale, by an intercepting conduit, passing from thence round the hills to Swindale, where the first auxiliary reservoir would be constructed, and on to Haweswater, the surface of which would be raised 42 feet, or to 736 feet above the Ordnance datum.

From the north end of Haweswater another intercepting conduit would be constructed, passing round the eastern slopes of Bampton Common, and conveying to that lake the waters of the Hows Beck, Gill Beck, and Heltondale Beck streams.

A third conduit or watercourse would be constructed from the river Lowther, commencing at a point about 1½ miles below the village of Askham, passing round the hill to the west of Clifton, along the eastern slope of the valley of the river Eamont, and terminating at the north end of Ullswater, into which lake and into the river Eamont it would deliver at Pooley Bridge.

These three conduits would intercept all the waters of the river Lowther and its tributaries above Clifton, and conduct them into the Swindale auxiliary reservoir, and into the Haweswater and Ullswater lakes.

From the north-western end of Ullswater a conduit would be constructed to Dacre Bridge, which would intercept and conduct into it the waters of the Dacre Beck and its tributaries.

Thirlmere would be raised 64 feet, or to 597 feet above the Ordnance datum, and from its northern extremity conduits or catchwater drains would be constructed in easterly and westerly directions; the first named would pass round the northern slopes of Matterdale Common, and intercept the waters of the Mosedale Beck, Trout Beck, ar Barrow Beck streams, and complete a zone of interceptir conduit and watercourse between the northern extremiti of Ullswater and Thirlmere lakes.

The other conduit or catchwater drain would pass rour Bleaberry Fell, and along the edge of the table-land east Watendlath, and extending up to the Blea Tarn wou intercept all the upper waters of the Watendlath and Col barrow Fells.

By constructing a tunnel from the south end of Thir mere under Dunmail Raise Pass, and some short inte cepting conduits from its southern extremity, the waters about six square miles of a very wet district on the southe face of the hills may be conducted to and impounded that lake.

When Thirlmere is full, or the streams in flood, the wate may be passed into a reservoir to be constructed on S John's Beck immediately below that lake, where they wou be impounded, and given out as compensation to the mil owners on the river Greta at and above Keswick; whe both are full the surplus waters may be passed into Ull water, which with the auxiliary reservoirs to be constructe in Martindale would, in conjunction with Thirlmere, l used for towns' supply only.

The waters of the river Lowther, although of admirab quality, are the least desirable in the scale of excellence, ar it is proposed to use them mostly for compensation, passir them in the first instance down the river Lowther itself t a point 1½ miles below Askham, from whence they would l conveyed by a new channel to Pooley Bridge, and the delivered into the river Eamont.

The water supplied to London and the intervening towr would be taken almost entirely from Ullswater and Thir mere lakes, and would be of extraordinary purity an excellence, being under two degrees of hardness, and co taining per imperial gallon not more than about four grai of total impurity, of which scarcely more than half a grai would be organic matter.

Haweswater and Thirlmere are lonely and unfrequente lakes, occupying deep valleys, embosomed in mountain and afford admirable sites for the construction, at comp ratively trifling expense, of immense reservoirs, to whic additional supplies of water can with great facility l conducted.

The particulars of the reservoirs would be as follows:—

Name.	Area of collecting ground in square miles.	Area of Reservoir in acres.	Contents in Cubic Feet. For supply to Towns.	Contents in Cubic Feet. For Compensation.	Total Storage.
Swindale -	38	166		187,000,000	187,000,0
Haweswater -		683	235,200,000	961,100,000	1,196,300,0
Martindale -	95	255	336,000,000		336,000,0

* If thought desirable, the waters from a further area of about eigh square miles draining into the Airy Beck and Dacre Beck, and no flowing into Ullswater, can easily be diverted and conveyed to Thirlmer

= to 120 days' supply at 250,000,000 gallons per day, and to 157 days' supply at 200,000,000 gallons per day—after giving credit for the average minimum summer yield, which will not be less than 40,000,000 gallons per day—and to 120 days' compensation at 450,000 gallons per square mile of drainage area; this will more than suffice in a district of such constant rain.

There would not be any necessity, in the first instance, for constructing the auxiliary reservoirs in Swindale and Martindale, as until the towns' supply exceeded 200,000,000 gallons per day Thirlmere and Ullswater would contain sufficient storage, and would be able, after giving credit for the summer yield, to work up to 135 days' supply, whilst compensation water would be given out from Haweswater and from St. John's Beck reservoirs; when the demand exceeds 200,000,000 gallons per day these auxiliary reservoirs may be constructed, and, if necessary, others in addition, as many sites are available; should the demand eventually exceed 250,000,000 gallons per day, a further area of 53 square miles of collecting ground may be obtained on the southern slopes of the range of hills above Ambleside and Kendal, by constructing reservoirs in the valleys traversed by the Troutbeck, the Kent, the Sprint, and the Bannisdale Beck streams, and an additional quantity of about 75,000,000 or 80,000,000 gallons daily may easily be obtained from these sources of supply.

As to the capability of the district no doubt therefore can exist, and it is worth consideration whether it might not be the wisest course in the first instance to construct those portions of the aqueduct which cannot be added to from time to time of sufficient capacity for this extended supply.

The surface of Ullswater lake would be ordinarily maintained at or about its winter level, and water drawn off from it for towns' supply at a depth of 20 feet, that is, at about 460 feet above the Ordnance datum; the shores, however, are mostly of a steep and precipitous nature, and any injury to the scenery or aspect of the lake would be more of a fancied than real nature.

Of course it would be impossible to carry out a scheme of this magnitude without doing some injury, but in the construction of these great reservoirs it would be reduced to a minimum; for instance, for Haweswater and Thirlmere, the total area of additional land required would not be more than about 750 acres, and there would be no residential damage. The number of houses which would be affected would not exceed 17 or 18, all of which, excepting three or four, are of the most ordinary class; and they can all, if necessary, be re-erected round the extended margin of the lakes.

At Ullswater the injury done, if any, would be very trivial. As long as the demand from the district did not exceed 200,000,000 gallons per day it would not be necessary to lower Ullswater at all until after a period of 67 days of absolute drought, Thirlmere being able to keep up the supply for that period of time; it would then take about 30 days more to lower Ullswater 8 feet, which would not be very much below its summer level; so that under these circumstances 97 days of continuous and absolute drought must occur before Ullswater would be sensibly affected.

When the demand has increased to 250,000,000 gallons daily, and the auxiliary reservoirs have been constructed, with their aid the towns' supply could be kept up from Thirlmere for a period of 70 days, and it would then take 23 days more to reduce Ullswater 8 feet, so that in this case 93 days of continuous and absolute drought would be necessary before the lake was reduced much below its summer level; and there is no record of drought of any such duration ever having occurred in this notoriously wet locality.

On this subject we are indebted to Mr. Samuel Marshall, of Kendal, who has been a careful observer of rainfall there since 1822, for the following valuable information:—

"The longest period of drought in this locality (Kendal), during the last 44 years, occurred in the spring of 1852, which, singularly enough, was also here the wettest year during that period.

"From the 19th February to the 29th April there were but three days on which rain fell, and the aggregate fall was only 0·21 inches, being a period of 70 days with less than a quarter of an inch of rain.

"The droughts next approaching this in duration occurred as follows:—

"In 1861, from the 1st April to the 8th June — a period of 69 days—there were but nine days on which rain fell, with an aggregate fall of 1·65 inches.

"In 1839, from the 28th March to the 4th June—a period of 67 days—there were but 12 days on which rain fell, with an aggregate fall of 1·97 inches.

"In 1826, from the 28th April to the 28th June—a period of 60 days—there were but eight days on which rain fell, with an aggregate fall of 1·12 inches.

"In 1829, from the 14th December to the 8th February 1830—a period of 55 days—there were but five days on which rain fell, with an aggregate fall of 0·65 inches.

"The years 1844, 1853, 1864, and 1865 were also dry years, but with droughts of much shorter duration than those above mentioned."

It must be borne in mind also that Mr. Marshall's observations relate to the rainfall at Kendal, which in many cases is not more than one-half of that in the mountainous districts above, where there is often a considerable amount of rain, whilst it is fine weather in the low country adjoining.

The water from Thirlmere would be drawn off at its northern extremity, and conveyed to Ullswater by conduit and tunnel; the tunnel would be eight miles in length, but shafts can be put down over the entire distance, and in such a case it is obvious there would be no greater difficulty in constructing a long tunnel than a short one; it is simply a question of greater length and of additional shafts.

From Ullswater the supply would be drawn off from the south end of the lake at Patterdale, and from thence carried by tunnel under Kirkstone Pass.

This tunnel would be the only work of unusual magnitude connected with the project; it would be 7¼ miles in length, but of this 5¼ miles would be ordinary and rather shallow tunnel, and would therefore present no difficulty; the central portion immediately under Kirkstone Pass would be 1¾ miles in length between the shafts, and would, at the rate of progress which has been effected at the Mont Cenis tunnel, occupy in its construction about three years after the shafts were sunk.

No doubt, with the rock-boring machines of the present day, it might easily be completed in that or a less period of time.

From the south end of the tunnel the water would be conveyed to London by conduit, tunnel, and iron pipes; the aqueduct would pass by Ambleside and Kendal, and down the eastern side of Lancashire, avoiding the Wigan coal-field, to the east of Manchester and of the Potteries district, and to the east of the Staffordshire coal-field and of Birmingham, and onwards towards London, following a route nearly parallel with that of the London and North-western Railway, and would terminate in a large regulating reservoir to be constructed to the north of Harrow, at a distance of about 12 miles from Cumberland Gate, Hyde Park.

The project may in fact be briefly described as an aqueduct, or arterial conduit, deriving its supply from the great rainfall and natural reservoirs of the lake country, passing through the heart of England, and capable of affording *in transitú* a practically unlimited quantity of the purest possible water to the vast manufacturing districts and population on the line of its route, as well as to the metropolis itself.

Some portions of the project and of the aqueduct may be carried out in detail, as the demand for water increases from time to time.

We now come to the consideration of the financial part of the scheme.

Of late years it has been pretty well recognized that all great projects of this and similar natures should be the property of the communities to whose necessities they minister, or in other words, that the consumers should be the proprietors of their own works, and guardians of their own interests.

It is also now equally recognized that the rates for water supply and drainage should be compulsory, and extend to all property within the area benefited. In different localities the rates are differently apportioned, but the principle is almost universally practised, and has been adopted in many large provincial cities and towns with great public advantage; it should, we conceive, *à fortiori*, be extended to the metropolis, and the water supply placed under the control of the Metropolitan Board of Works, or of a similar board, to be elected for the purpose, from the ratepayers themselves.

In this case it would of course be necessary to purchase the existing waterworks and incorporate them with the new project, securing to the different companies the net incomes they at present enjoy.

We learn from the pamphlet recently published by Mr. Bateman, C.E., on the water supply of London, that these in the aggregate amount to rather more than 400,000*l.* per annum, whilst their gross receipts are about 700,000*l.*, or nearly 1*s.* in the pound, on the present rateable value of the property in the metropolis, which amounts to about 15,000,000*l.* annually, and this would no doubt reach to a much larger amount by the time these proposed works were completed. We shall call it then 16,000,000*l.*, although, judging from the late ratio of increase, this would evidently be below the mark.

The cost of the project complete for a daily supply of 250,000,000 gallons, we estimate at 12,200,000*l.*

As, however, there would be no necessity for bringing the whole of this large quantity of water before the demand for it had actually arisen, we shall assume that 200,000,000 gallons only are brought in the first instance; that is—

	Gallons.
For domestic consumption - - -	120,000,000
For public and trading purposes - -	30,000,000
For sale to population on line of conduit	50,000,000
Total -	200,000,000

The cost of which would be—

Conduits, reservoirs, and works of collection - - - - - - -	£675,000
Tunnel from Ullswater to Ambleside -	350,000
Aqueduct to London - - - -	8,125,000
Regulating reservoir, &c., near London	500,000
	£9,650,000
Interest on unproductive capital during an average period of three years, and other expenses - - - - -	1,550,000
	£11,200,000

The annual expenses would probably be—

Interest on 11,200,000*l.* at four per cent. -	£448,000
Collection, management, and casual repairs	100,000
Present dividends to water companies -	425,000
	£973,000

To meet this we should have, after the works have been for some few years fairly in operation, a probable income of—

From the sale of 50,000,000 gallons daily, to towns, &c., on the line of aqueduct, at 3*d.* per 1,000 gallons -	£228,125
From the sale of 30,000,000 gallons daily in London, for public and trading purposes, at 3*d.** per 1,000 gallons - - - - -	136,875
From an average rate of 10*d.* in the pound on a property of 16,000,000*l.* -	666,666
	£1,031,666

which is 58,666*l.* in excess of what is required, as shown above.

In the estimate of income no credit is taken for the annual value of the assets and property of the water companies, which it would not be necessary to retain after the introduction of the new water supply.

This average rate of 10*d.* in the pound may be levied as may be deemed most equitable, say a 9*d.* rate for domestic consumption on an assumed house property of 12,000,000*l.* and a public rate of 3*d.* on a total property of 16,000,000*l.*, this would amount—

For the domestic rate, to - -	£450,000
For the public rate, to - - -	200,000
Total - -	£650,000

which would probably suffice.

It is not, however, to be expected that the 50,000,000 gallons daily proposed to be sold to the towns and populations on the line of the aqueduct could be disposed of all at once, and in estimating the rates likely to be levied on the citizens of London we must take that into account, and we shall now consider the question as if no water were disposed of.

This would leave a sum of 973,000*l.*—136,875*l.*=836,1 to be levied on the metropolis, and would amount to average rate of rather more than 12½*d.*, say 1*s.* 1*d.* in pound on all property; this would be the maximum r which under the most unpropitious circumstances it wo be necessary to levy and which would not amount to m than the actual rate now levied on property in the met polis by the existing water companies.

It is more than probable, however, that by the time th works were completed the rateable value of the metropoli districts would amount to 18,000,000*l.*, of which probal three-fourths, or 13,500,000*l.*, would be house property, a in this case, if no water were sold on the line of aquedu the rate necessary to be levied would amount to about 11 in the pound.

If the rateable value amounted to 18,000,000*l.*, a 25,000,000 gallons were sold daily on the line of the aqu duct, the necessary metropolitan rate would amount nearly 9¾*d.*, say 10*d.* in the pound.

If, however, the sale of water on the line of aqueduct h increased to 50,000,000 gallons daily, and the rateable val of the metropolitan districts had increased to 20,000,000 —events by no means improbable—the average necessa rate would not then amount to more than about 7½*d.*, s 8*d.* in the pound, and this would gradually be diminishe as the rateable value of the metropolitan districts, cause by suburban extensions, and the springing up of a new ar better class of property in the metropolis itself, progressed and to meet the future demands likely to arise from the and other causes, there would remain a further quantity 50,000,000 gallons daily, to be supplied at an outlay 1,000,000*l.*, which may be expended when the necessit arises.

On the subject of diminution of disease, of poors' rate of fire insurance, and of taxation generally, consequent o the introduction of a plentiful supply of pure water, no re marks are necessary: such results are too well known t require comment.

We trust we have shown, that not only is London withi the pale of an admirable supply, but that water of extra ordinary purity and excellence may be readily procured an distributed to its inhabitants at rates of charge at leas equally moderate with those at which other large towns ar supplied, and under no circumstances exceeding the rates levied for the present intermittent and unsatisfactory supply

In the autumn of last year, when the plans and general features of this scheme were nearly matured, a letter from Mr. G. J. Symons, the well-known meteorologist, appeared in one of the public journals; in it was mentioned the feasibility of procuring water from the Westmoreland and Cumberland hills for some districts in Lancashire, at that time suffering from drought, and since then the subject appears to have been taken up by Mr. Dale, C.E., of the Hull Corporation Waterworks; some particulars of a project for the purpose, put forward by that gentleman, having appeared from time to time in the scientific journal known as "Engineering."

Mr. Dale's project, as far as we can gather, is to supply a number of towns in Lancashire and Yorkshire from Haweswater and Ullswater lakes; but, excepting in the circumstance of these lakes being included in our scheme and forming a portion of it, there is no similarity or affinity between the respective projects.

G. Willoughby Hemans.
Richard Hassard.

APPENDIX G.

Letter from Dr. Clark, on the Hardness of Water.

Clyde View, Partick, near Glasgow,

My Lord Duke, 30th October 1867.

If I take the liberty of addressing your Grace in your capacity of Chairman of the Royal Commission on the Supply of Water to the metropolis, it is as an old man of science that has performed a variety of service relating to the supply of water to towns, and for the benefit not of myself but of the consumers.

In order to explain the long and persistent interest I have taken in the supply of the metropolis with pure water, I may be allowed to state that happening to be in London so far back as the autumn of 1839, I accidentally saw a Parliamentary Blue Book, then just out, on the water supply of the metropolis. For the benefit of my pupils I had been accustomed to go rather fully into the treatment of water for the use of towns, and I procured the work, chiefly with a view to improving my lectures.

This Blue Book, however, opened to me a new field of information in regard to water for towns. The waters treated of were of the kind yielded by the chalk geological formation, of which hardly a trace occurs in Scotland.

Struck with the great hardness of the London waters, owing to the chalk they contain, the question occurred to me, how far hardness of this description could be got rid of? To this question I applied myself with diligence, and in the following March I was able to take out a patent for a process to soften chalk waters. In due time the specification was entered, wherein was first published a method of expressing hardness numerically in degrees, which since then has recommended itself to general adoption.

It is not my desire to intrude on your Grace with a discourse on water in general, but only to call your attention to a process for the purification of water that is of supreme importance in considering the question of the satisfactory supply of water to the metropolis. For this purpose it will be necessary to glance at the chemical composition and some of the chemical properties of chalk; for while chalk makes up the great bulk of the matter to be separated, chalk also contains the ingredient that brings about the separation. The invention is a chemical one for expelling chalk by chalk.

Chalk, then, for every pound weight of 16 ounces consists of lime nine ounces, of carbonic acid seven ounces. The nine ounces of lime may be obtained apart by burning the chalk, as in a lime-kiln, but may be subsequently dissolved in water in any quantity not less than 40 gallons. The solution would be called lime-water. During the burning of the chalk to convert it into lime the seven ounces of carbonic acid is driven off. This acid when uncombined is naturally volatile and mild; it is the same substance that forms what has been called soda-water, when dissolved in water under pressure.

Now so very sparingly soluble in water is chalk by itself that probably upwards of 5,000 gallons would be necessary to dissolve a single pound weight; but by combining one pound of chalk in water with seven ounces additional of carbonic acid, that is to say, with as much more carbonic acid as the chalk itself contains, the chalk enters readily into solution with water, and when so dissolved is called bicarbonate of lime. If the quantity of water containing the one pound of chalk with seven ounces additional of carbonic acid were 400 gallons, the solution would be a water of the same average hardness as well-water from the chalk strata, and not sensibly different in other respects.

Thus it appears that chalk, although naturally hardly soluble in water, may be rendered freely soluble in it by either of two distinct chemical changes, soluble by being deprived entirely of its carbonic acid, when it forms lime-water, and soluble by combining with a second dose of carbonic acid, making up bicarbonate of lime.

Now when we mix together these two varieties of solution of lime in water in such proportions as that the lime-water and the bicarbonate of lime contain each the same quantity of lime; for instance, when 40 gallons of clear saturated lime-water is mixed with 400 gallons of clear chalk spring water, each containing nine ounces of lime, the ingredients in solution combine so as to form two pounds of chalk, producing a sort of whitewash, which soon subsides into a powder of chalk, leaving clear pure water above. The following table will show what takes place when this change occurs:—

	Agents.		Products.	
Bicarbonate of lime	Chalk with Carbonic acid	16 oz.	= 16 oz. of chalk	2 lbs.
Burnt lime in 40 gallons of lime water		9 oz.	=16 oz. of chalk	

Rigid accuracy requires us to take into account the slight quantity of chalk that water can hold in solution, say a grain and a half per gallon = 1½ degrees of hardness.

In a year or two after the invention of this process, which was the last of a series of overworkings of the brain by the inventor during a period of at least 20 years, I was laid up and had the mortification of being permanently disabled from teaching. It was the year 1849 before my health permitted me to return to London. Ere then the process had attracted some degree of public attention. I had published a pamphlet that went through three editions, giving a popular account of the process and of its advantages. In 1851 a Government Commission was appointed to examine the "chemical quality" of the waters proposed for the supply of the metropolis. The Commissioners were Professor Graham (now Master of the Mint) and Doctors Miller and Hofmann. I am not aware of any Commission ever appointed by the Crown, to ascertain facts falling within the range of chemical science, consisting of persons more competent, or of higher scientific authority.

These eminent gentlemen were pleased to report thus:—

"In the judgment of the Commissioners *this softened chalk* "*water is entitled, from its chemical quality, to a preference* "*over all others for the future supply of the metropolis*" (Report, page 44).

It was not unnatural for an inventor that had laboured, I might say had sacrificed his means and his health, in order to render his invention efficient, to receive with gratification such an expression of approbation from such men: but how could he fail to be mortified when he subsequently beheld Government acting contrary to the opinion of eminent and impartial judges appointed by themselves?

The opinion of these eminent chemists has been amply verified by several erections of waterworks expressly for conducting the softening process. All these erections have been made, and most efficiently, by one engineer, Mr. Homersham. Not one of these works has proved a failure. The whole series might on the contrary be quoted as one of uninterrupted success. Three of the works are within an hour or two's journey from London, and I have no doubt that Mr. Homersham will be ready to facilitate to your Grace, or to any or all of the other Commissioners, the satisfactory inspection of any one or more of these works while in operation.

When I first invited public attention to the process for the use of the metropolis, I assumed that it would be river water, such as the Thames, that the process would naturally be employed to improve. But much about the time when the softening process was contrived the late eminent civil engineer, Robert Stephenson, had with his usual talent organized, matured, and defended a project for obtaining uncontaminated spring water for the supply of the metropolis from the chalky portion of the vast basin whereof London is the centre. Relinquished by Mr. Stephenson on account of his numerous engagements of another kind, and delayed by circumstances, this project gradually and worthily came into the hands of Mr. Homersham. He was the first to call my attention in 1849 to the expediency of confining in the neighbourhood of London the application of the softening process to spring chalk-water. Indeed the exclusion of the scourings of occasional showers, and the entire absence of animalcules and other organisms, are very signal advantages, and at once put a mark of superiority on the waters raised from the depths of the chalk. In spring chalk-waters the minute proportion of organic matter

destructible by a red heat, but previously removable by the softening process, amounts generally, according to my experiments, to about a full grain per gallon, so that the softened water is to this extent rendered more free from organic matter than the unsoftened spring water.

But it is not alone on account of the exclusion of rain-scourings or of organisms that spring water from the chalk derives its superiority, it is also on account of the prevailing temperature of the springs, which around London is generally about 50° Fahrenheit. Each spring keeps very near its own normal or standard temperature all the year through, whereas any river or other surface water, such as may now or may hereafter be brought into London, will in summer be too hot and in winter too cold for drinking, and moreover will in winter be liable to cool down below the freezing point, causing numerous burstings of the pipes by the freezing of the water they contain, and even by accidental explosions, so far as provision is made for heating the water for domestic use. This defect is inseparable from river and all surface waters introduced into towns, and attracts the less attention in the projects of waterworks, inasmuch as the expense of repairs thus incurred falls to be paid by the consumers and not by the companies. But apart from the serious expenses thus incurred, the damage to houses, the damp, the temporary interruption of all supply of water, are most serious drawbacks to any scheme of constant water supply. Spring water when passing through mains and pipes 4 feet underground, which is Mr. Homersham's practice, is free from any but rare and accidental instances of such defects. So treated the softened chalk-spring water is found all the year through not to rise above nor yet fall below the normal temperature of the spring more than six of Fahrenheit's degrees.

I shall be happy if your Grace deem these facts and considerations worthy of the attention of the Commission over which you preside.

I have, &c.,
THOS. CLARK.

To His Grace the Duke of Richmond, &c. &c. &c.,
Chairman of the Royal Commission on the
Supply of the Metropolis with Water.

APPENDIX H.

MEMORANDUM by Mr. JOHN BRAVENDER on the Upper Part of the Thames Basin.

As the subject of water supply to the inhabitants of towns generally, together with other sanitary improvements, has lately occupied public attention and is most certain to continue to claim more notice than ever, I hope to be excused for venturing to send you a few remarks and observations on the subject, and particularly with regard to the watershed of the Upper Thames, that is, of the country between the sources of the Thames and the city of Oxford.

The general course of the Thames is eastward. It is not derived from any defined spring at its head, giving out all, or nearly all, its waters, but is fed by many small rivers and brooks, most of them having their courses from the north and running southward, or having their courses from the south and running northward.

The Thames, according to the Ordnance map, commences at a place called Waterhay Bridge, about a mile below Ashton Keynes village, and about three miles west of Cricklade. The river, brook, or stream above this point is called Swillbrook, which is joined by a brook running from "Thames Head," past Kemble, through Somerford Keynes, and which joins the Swillbrook about a mile below Somerford Keynes village, and by another from Braydon, which joins the Swillbrook a little above Waterhay Bridge. The area of the watershed of this district, called "Swillbrook and Thames Head," is 74 square miles.

The following are on the north side of the Thames, and fall into it by taking generally a southward or south-eastward course:—

The Churn.
Ampney and Marston Brooks.
The Coln.
The Leach.
Small streams in Bampton district.
The Windrush.
The Evenlode, Glyme, and Darne.

Beyond the watershed of the Evenlode is that of the Cherwell, but as this river falls into the Thames below Oxford I have not considered it in the Upper Thames area.

The following are on the south side of the Thames, and fall into it by taking a northward or north-eastward course:—

The Ray.
Small streams in the Highworth district.
The Cole.

Beyond Faringdon the Ock has its rise and falls into the Thames at Abingdon below Oxford, and therefore beyond the district which I have named. The watershed of the Ock contains 100 square miles.

The springs of the watershed, containing 123 square miles, on the south side of the Thames, are not so abundant as from the same quantity of square miles on the north side of the river. The dip of the strata is south-eastward, and descending from the Thames on the south side, but towards the Thames on the north side. The surface slopes from the chalk hills towards the Thames, and the water which immediately runs off reaches the Thames, but at a slower rate than that from the north. Part of that which is absorbed by the soil, and part which is lost in the streams in the passage over open and porous beds, sinks through those porous beds to the upper surface of the tenacious beds of the Oxford Clay, Kimmeridge Clay, and the Gault, and the water descending the plane of stratification in a contrary direction to that of the river is lost to the Thames. The same remarks refer to the watershed of the Ock.

I have separated the district called Bampton from that of the Windrush and of the Evenlode, because the brooks and rivulets in it do not finally form a river of much larger size, and then pass on and into the Thames; but several small brooks take their course into the Thames without uniting, and this renders it incapable of being designated the watershed of any particular brook or river.

The same will refer to the district called "Hishworth."

The area of the watershed of the Upper Thames thus described is 875 square miles, and is made up as follows:—

	Square miles.
WEST OF THE THAMES.	
Swillbrook and Thames Head	74
NORTH OF THE THAMES.	
The Churn	73
Ampney and Marston Brooks	32½
The Coln	87
The Leach	36½
The Bampton and Thames district	119
The Windrush	141
The Evenlode	189
SOUTH OF THE THAMES.	
The Ray	65½
Highworth district	9½
The Cole	48
	123
	875

The rainfall over this 875 square miles may be taken at 28 inches per annum, from which 12 inches should be deducted for evaporation. The rainfall on a square mile, with this deduction, will be 1,376,000 cubic yards. But to arrive at the probable available quantity a further deduction should be made for percolation into porous strata which may not afterwards be thrown out by springs, and in consequence may not reach the Thames but pass under it. Some of this water we know must be brought to the surface by faults, as at Boxwell spring; but this can only be part of what percolates through the beds of the upper oolite to the surface of the fuller's earth. The water which is absorbed by the very porous beds of the under oolite is very large, amounting to a third of the rainfall.

The Churn, Coln, Windrush, and Evenlode, descend through valleys of denudation, the under oolite being cut through to some depth below the junction with the lias and a large quantity of the under oolite. Rainfall finds its way into those rivers by springs on the sides of the streams, and particularly by springs on the north-western side of the narrow valleys through which they pass; but some of this is liable to be absorbed again in its passage over the under oolite which occupies the beds of those rivers below the junction.

The loss by percolation through the upper oolite, including the forest marble and combrash, is to a considerable extent compensated by the immense discharge from the fuller's earth by Boxwell, Ewen, Ampney, and Bibury springs, which water, if not so discharged, would pass down the plane of stratification, and would not appear again in the vale of the Thames; and added to which must be reckoned half of the water pumped up from the fuller's earth by the engine at Thames Head. The summit level of the Thames and Severn canal extends from Daneway, at the western end of Sapperton tunnel, to Siddington, near Cirencester, being about 8 miles in length. From those two extremities the canal descends westward towards the vale of the Severn, and eastward to the vale of the Thames at Lechlade. The water being retained on the summit by means of locks, it descends in either direction about half to the Thames and the remainder towards the Severn. The principal loss in the watershed of the Thames occurs in the under oolite, the area of which is about 106 square miles. I have many years been aware of the great loss of water in the Churn, Coln, Windrush, and Evenlode, by passing over the open and rubbly rock of the under oolite, but until 1859 did not succeed in getting the occupiers of the mills on those streams to fix on the right cause. And this was not accomplished without a thorough investigation of the Churn, in which I lent a helping hand, and which finally established the views I had for years previously entertained. The observations were made in the autumn of a very dry summer, and the loss ascertained must be taken to be the maximum, and what the minimum may be is uncertain.

The average yearly loss I think is not less than half the rainfall, after deducting for evaporation, leaving 8 inches of available water. The available depth over the other strata in this watershed may be taken at 12 inches. The mean would appear to be somewhere between 9 and 11 inches.

Assuming it to be 9 inches only, and the inhabitants of London to be 3,250,000, then 272 square miles of watershed at this depth will supply them with 30 gallons each per day.

It will thus appear that the watersheds of the Churn, Ampney, and Marston brooks, the Coln, and of the Ock, amounting to 292½ square miles, will more than supply the entire population of London. The Churn, the Coln, and the Windrush, having an aggregate watershed of 301 square miles, are more than sufficient for the purpose, and the watersheds of the Churn, Coln, and the Ock, containing 260 square miles, are nearly sufficient for the purpose. London is at present said to be supplied with 643,000 cubic yards of water daily, which is at the rate of more than 33 gallons per head for 3,250,000 inhabitants. If this be correct, London is more abundantly supplied than many other towns.

But there is no necessity to provide the means of supplying the entire population of London. There are already eight or nine water companies, and I think to supply one-third, or to add one-third to the present means, would insure an abundance. In such case it would only be necessary to provide for 1,000,000 of the inhabitants. Eighty-four square miles of watershed will supply 1,000,000 people with 30 gallons per head per day. And to effect this there will require to be abstracted from the Thames directly, or intercepted at the confluence of the Windrush, a little more than half its water; or at the confluence with the Coln nearly all its water; or at the confluence with the Ock four-fifths of its water; or to be taken from the Churn and Ampney brooks, four-fifths of their waters. The water would have to be taken to London by an aqueduct, conduit, or pipes, and this may be accomplished without the help of steam or any other power. There is a fall from the mouth of the Coln to Paddington of about 3 feet per mile, which is sufficient to convey the water and distribute the same over any part of London which is at a lower level than Paddington by the force of gravity alone, which power costs nothing.

I think few persons will be disposed to doubt that by proper management under the Thames Commission this quantity can be spared from the river with little or no effect on the Thames itself.

I am prepared to show that with a very moderate expenditure the quantity of water descending the Churn and Coln may be greatly increased, and a very large quantity sent down to the Thames which is at present absorbed in the passage over the under oolite rock, which is very porous in this district. The increase which may be obtained from the Churn alone will be sufficient for more than 500,000 inhabitants, but which is now lost to the Thames.

The conveyance of this 84 square miles of rainfall to London may appear to present insuperable difficulties. There are difficulties, but I think not greater than those of an ordinary kind. For the purpose of carrying out this scheme I should recommend the formation of a new water company, whose engineers would soon show how to overcome the difficulties, if there are any.

In ordinary seasons there is an abundance of water in the Thames and its tributaries, but in times of a long continuance of dry weather it diminishes considerably, and in consequence storing will be indispensable in two of the following schemes:—

1. At a place called Langley Wear, near Appleton, in the county of Berkshire, and nearly opposite the place where the Windrush joins the Thames, about 7 miles below Witney, the water may be taken directly from the Thames and conveyed by conduit or otherwise in a straight line to near Didcot Station on the Great Western Railway, and thence by the side of the railway to Paddington.

By the Great Western Railway it is 53 miles to Didcot, and from Didcot to Langley Wear 9 miles, making the distance from Langley Wear to Paddington 62 miles.

The water may be stored for use in dry seasons at or near London, or at one or more places on the line of conduit between Langley and London.

2. At the confluence of the Windrush with the Thames the water of the Windrush may be taken and conducted to Paddington as above, and reservoirs for storing made either at the mouth of the Windrush, at or near London, or in both places, or at other places on the line between Langley and Paddington. The distance, as above, is 62 miles.

3. At the mouth of the Coln, about a mile above Lechlade, a reservoir may be constructed, into which may be conducted the waters of the Coln, the Ampney brook, and the Churn. Those rivers would have served all the purposes of the inhabitants on their courses previously to reaching the points where it will be desirable to divert them, and there would be no objection to the water being retained in a reservoir previously to the usual dry season of the year. The water may be conducted through the valley of the Thames to the previously mentioned point on the river called Langley Wear, and thence it might be taken to Paddington, as before stated. The distance from the mouth of the Coln is 72 miles, and the fall from Lechlade to Langley Wear 20 inches per mile, and from Langley Wear to Paddington 3 feet per mile. The mouth of the Windrush is very well suited for a large reservoir, and the mouth of the Coln is most favourable. The Cole joins the Thames at or near this spot, but on the opposite side, and in case of need could be made use of. Steam-engines might be placed so as to pump from the fuller's earth a little south-eastward of the "Thames Head," and the water thus obtained would descend through pipes to the reservoir at the confluence of the Coln with the Thames. It will be necessary to store up water for six weeks or more, and this may probably be done at both ends of the works, or at one end, or at intermediate places, to provide against unusual and extremely dry seasons.

The proposed lines of conduit will cross the river Ock at or near to Marcham Meadow Farm, 2 miles above Abingdon, at which place a large quantity of water may be taken and sent on to London if it should be required.

A million of inhabitants require 178,000 cubic yards per day, and 42 times this would have to be stored. Reservoir room would therefore have to be provided for 7,000,000 or 8,000,000 cubic yards of water. Should larger reservoir accommodation be necessary it may be had to any extent. It is only a question of expense.

The impurity of the water of the Thames has been spoken of by writers on the subject, but the passing of a recent Act of Parliament will tend greatly to remedy this. The smaller towns on the tributaries beyond the three-mile limit are preparing for the disposal of the sewage by other means than letting it descend into the streams running near or through them.

I should think that any company formed for the purpose of supplying this million of the inhabitants of London would be willing and could afford to pay an acknowledgment to the Thames Commissioners for the privilege and as compensation for being allowed to take this water from

the Thames. The quantity to be taken per annum would be more than 65,000,000 cubic yards, and the payment of a very small fraction per yard, say one penny for 90 cubic yards, would create a revenue of 3,000*l.* a year. The yearly income of a water company at 5*s.* per head for a million of people will be 250,000*l.*

This 3,000*l.* a year would enable the Thames Commissioners to improve the river, and in doing so very greatly to improve the lands on its banks. This would be a beginning; but the works should not be limited to an outlay of a small sum per annum to effect the improvements to which the Commissioners should direct their attention.

The river from Cricklade to Oxford should be straightened, deepened, and in some places widened, and the inlets of all rivers, brooks, and streams would have to be deepened to correspond on both sides for some way up their course. Without going over the ground it will not be easy to say what the cost of these things will be or ought to be, but I have an idea that 140,000*l.* or 150,000*l.* would carry out what is here indicated. This money would have to be borrowed, and reckoning at four per cent. on 140,000*l.* the interest would come to 5,600*l.* per annum. A rate of 2*s.* 3*d.* per acre on 50,000 acres of land between Cricklade and Oxford, which would be greatly improved by the works, will amount to 5,625*l.* This would be a very moderate charge on the land, the greater part of which would be increased in value to the extent of from 5*s.* to 1*l.* per acre per annum. The rate would have to be risen on the lands in proportion to the extent of the improvement of each field by the works, and not on an average of the district to which the operations may extend.

The 3,000*l.* a year which is proposed to be derived from a future water company would meet the official and other expenses, and leave something to form a fund for future repairs, extensions, and improvements of the works, and any excess might accumulate and be used from time to time in reducing the borrowed capital.

JOHN BRAVENDER.

Cirencester, April 1867.

APPENDIX I.

(REPRINT OF PAMPHLET.)

On a CONSTANT WATER SUPPLY for LONDON.—By JOHN FREDERIC BATEMAN, Esq., C.E., F.R.S., F.G.S., &c.

(*Reprint of a Paper read at a Meeting of the Health Department of the National Association for the Promotion of Social Science, Monday, January* 21*st*, 1867.)

THE question of "Constant Water Supply" is one which has been agitated, not only recently, but on many previous occasions in London, and in those places where the opposite system of "intermittent supply" has been the mode usually adopted. I have been requested to read a paper upon the subject; but as my experience lies almost wholly with the system of "constant supply," I can do little more than state how far it has been successful, and what are its results in the cities and towns with which I am acquainted, and describe what are the difficulties with which a town has to contend when the supply is changed from the "intermittent" to the "constant" system. Coming before you as a comparative stranger, known only by name, but probably presumed to have a certain amount of professional knowledge upon the subject, it may be expedient that I should state to you what my experience is, that you may be able to judge of the value to be placed upon the observations I may make.

I first constructed works for the supply of water to towns nearly 30 years ago—since which time I have constructed, in whole or in part, the waterworks of some 25 or 26 different towns and cities, varying in size from 7,000 to 600,000 persons, and containing a gross population of upwards of 2,000,000. I have, besides constructing these works, been consulted in one way or another upon a great number of the waterworks of the country, which have been in the charge of other engineers, during the period named, and I ought therefore to know something of the subject, unless I have made very bad use of my opportunities.

My experience commenced in the manufacturing districts of the north of England, and at the time of its commencement, 25 or 30 years ago, the question of water supply was in a very crude condition. The system commonly adopted, however, even then, in that part of the country, was that of "constant supply," and in my early experience I neither thought of nor knew anything of any other system. In all the towns that I have supplied there are, I believe, but three which at the present time give an intermittent supply of water, and these are towns in which waterworks existed, and the intermittent system was established, before I had anything to do with them. In one of these, the town of Belfast, the system will be discontinued as soon as new works, now being constructed, have been completed. In many places, and most importantly, those of Manchester and Glasgow, I have been instrumental in changing the mode of supply from the intermittent to the constant system; and it is my experience specially with reference to these cities and the change of systems that I shall endeavour to lay before you.

The question of constant supply is one which most materially affects the comfort and convenience of the poorer classes, and the inhabitants of smaller houses. In larger houses ample cistern space is generally provided, to secure the equivalent of a constant supply; but where water is constantly laid on from the street mains, there is scarcely any occasion for house cisterns, except for the supply of water-closets. By proper arrangement, little or no inconvenience is experienced from the occasional shutting off of water for the changing or attaching of house services. The first cost of introducing the water to the houses is reduced to the lowest possible point, and the pollution which more or less commonly attends the storage of water in house cisterns is entirely prevented; the water is delivered in the purest, freshest, and coolest condition; and very much of the annoyance and inconvenience arising from frozen cisterns and burst pipes, which are the common attendants of the winter season, is avoided. There is no occasion for exposed pipes in out-of-the-way places—for cisterns in roofs or on the tops of houses, to be filled with soot and dust in summer, and to be frozen in winter; and a man may live in tolerable comfort, without the dread of the water bursting above his head, and deluging the apartment in which he resides. But the advantage of constant supply to the consumer has been so often and so clearly demonstrated, that it is useless to dwell further on this branch of the subject. The question of its adoption does not entirely rest with the consumers, but with those who have to provide the water. It is believed by many, that the consumption under the constant supply system is so great, that no company or waterworks can meet the demand—it would be ruin to them if they attempted it. I cannot but think that all this is a delusion; it is not that more water is actually consumed for the use of the individual under the one system than under the other, but that the amount of *waste* which results from bad pipes and bad fittings, constantly supplied with water, is so great as to occasion serious loss and inconvenience to a water company, and perhaps in some cases to exhaust their supplies. The experience of those towns in which the supply has always been on the "constant system," and where every precaution has been taken for the purpose of securing good workmanship, the best and strongest materials, and the most improved apparatus, is, that the consumption of water per head is certainly not more, probably less, than it is in towns similarly circumstanced in all other respects, but supplied with water on the intermittent system. This is abundantly proved by the statistics of water supply in such places. For instance, the average consumption of water in the manufacturing towns of Lancashire and Yorkshire is from 16 to 20 or 21 gallons per head per day for all purposes, including trade, and of course all the waste which may be taking place. In Manchester, the quantity consumed by about 600,000 persons, and by the trades demanding water within the district supplied, varies from 12,000,000 to 13,000,000 gallons per day. Of this quantity, it is estimated that one-third is supplied to manufacturers, leaving the net quantity consumed for domestic purposes, including waste, 14 gallons per head per day.

The experience of Preston, Blackburn, Bolton, Stockport, Halifax, Warrington, and almost all the other manufactur-

ing towns in the north of England is nearly identical with that of Manchester—and if this be compared with the consumption which obtains in towns supplied under the intermittent system, it will be found that scarcely in any case does the supply fall to so low a point as under the constant system.

In London it is 32 gallons per head per day, and in Plymouth, Devonport, Shrewsbury, Oxford, and other places supplied on the intermittent system, the consumption amounts to 30 gallons or more per day.

The quantity required in different towns no doubt varies according to the class of inhabitants, the circumstances, and the habits of the people, and it is universally found that where water-closets exist as a general rule, the consumption is greater than where they are comparatively absent.

It may be well, therefore, to adduce a few examples of what is actually required for domestic use.

We have shown that in the manufacturing towns with an unlimited and unstinted supply, 14 gallons per head per day are all that are taken for domestic use. In Preston, careful observation and measurements, continued during many years, proved that 10 or 11 gallons were sufficient. But in these towns generally the number of water-closets is small.

The results of a few experiments which were made in Sheffield some six or seven years ago will be instructive. Two groups of cottages and a single mansion were selected for experiment; the water was constantly laid on; in one case the consumption was taken by actual measurement, by means of a cistern, and in the other two cases by a water meter. The experiments were made without the knowledge of the inhabitants. One was a case of 16 cottages, containing 83 inhabitants, and in these the average consumption upon a fortnight's trial was 7½ gallons per head per day. The second case was a group of four houses each of about 25*l.* a year rental, containing 26 inhabitants, and here the consumption for a similar period was at the rate of five gallons per head per day. The third was that of a large mansion with 13 inmates, a bath, and two water-closets; here the consumption was at the rate of 11 gallons per head per day. The average consumption in the town of Sheffield, including the supply to trade, was 20 gallons per head per day; deducting the trade supply as ascertained by meter, it was 18 gallons per head per day; but the pressure in Sheffield is, with perhaps two or three exceptions, greater than that of any town in the kingdom, and any leakage therefore which might have existed, and which of course would be included in the 18 gallons per head per day, would be much greater than in a town where the pressure does not exceed that to which pipes are ordinarily subjected.

Other instances of what is actually required will be given when we come to treat of the prevention of waste; but it must be clear that there is nothing in the system of constant supply which would necessarily create a larger consumption of water than in that of the intermittent supply. Anything beyond the proper normal requirements of the inhabitants, which would be amply met by from 15 to 20 gallons per head per day even in a town largely supplied with baths and water-closets, is chargeable to defective pipes or defective arrangements and fittings: and now we come to the real difficulties with which the system has to contend.

On this point and on the extent to which waste may be reduced, I can give several useful examples.

In Cambridge, where the supply has always been constant, but where precautions against waste were neglected till recently, the following facts are exhibited, for which I am indebted to Mr. Tomlinson, the manager. In the first half-year of 1865, at which time no preventive measures had been introduced, the gross consumption per head per day was 31·2 gallons, and the domestic consumption, after deducting water sold for trade purposes, 23·1 gallons per head. A house to house inspection was then carried out—all bad cocks were replaced by those of the best construction, and water-fittings of every description were put into proper repair. The result was, that in the first half-year of 1866, the gross daily consumption was reduced to 19·56 gallons per head, and the domestic consumption to 11·1, being less than one-half of what had previously obtained.

At Newcastle-on-Tyne the water has always been delivered on the constant supply system; but the consumption gradually increasing to an extravagant point, a vigilant inspection was introduced, and means taken for checking the wasteful expenditure of water, sufficient powers having been granted to the company by a recent Act of Parliament. Mr. Main, the very intelligent manager of this company, writes me as follows:—

"Our gross daily consumption is 30 gallons per head, of which seven gallons go to manufacturers and trade. Considering 23 gallons per head to be excessive for domestic consumption, I was anxious to ascertain precisely where the water went to. For this purpose I had the town divided into small districts of three or four streets completely isolated, and put on a street meter to register the daily consumption. On comparing the results in districts where water-closets prevailed with those in which there were none, or comparatively few, it was soon apparent that the water-closet, generally from being out of order, but in several cases from the crank handle being purposely propped up, was the great consumer. The following are a few of the results:—

	No. of Inhabitants.	Water Closets.	Consumption per head per day.
1. Eldon Square - - -	170	29	70 Galls.
2. Leazes Terrace - - -	275	47	71 ,,
3. Rye Hill and adjoining Streets	880	118	55 ,,
4. Framlington Place and do. -	770	124	80 ,,
5. North Parade and do. -	725	173	60 ,,
6. York Street and do. -	190	25	61 ,,
7. Lancaster Street and do. -	145	12	62 ,,
Prudhoe St. and adjoining strts.	1575	10	11 ,,
Thornton Street and do.	1930	None.	23 ,,
Abinger Street and do.	1595	33	30 ,,
Shield Field District - -	4845	138	21 ,,

"In order to stop so flagrant a waste we set on a staff of men to examine every water-closet and tap, and report them, leaving a notice, that if not put in order within three days, the supply would be stopped, After the lapse of three days, another set of men followed, inspecting only those places reported as leaking, and shutting off the water where the notice had been disregarded. In this way we stopped an immense waste, the effect being immediately apparent in increased pressure throughout the town. But that measure was only for a temporary purpose, and could not be relied upon to effect any permanent saving, and for upwards of twelve months we have been going on systematically replacing the present water-closets with Guest and Chrime's double-valve cistern, and Thomson and Murray's valve cistern, neither of which can be propped to cause a continuous run. In this way we have reduced

"No. 3 District from 55 to 34 gallons per head.
5 ,, ,, 60 ,, 39 ,, ,,
6 ,, ,, 61 ,, 25 ,, ,,
7 ,, ,, 62 ,, 26 ,, ,,

"The others are not so complete that I can give you the results accurately.

"In carrying out the change, we occasionally meet with opposition, but not as yet to any extent. In one district we put new double-valve cisterns into every house by arrangement with the landlords. The result was as follows:—

"Tyneside Terrace and Mitford Street—number of inhabitants, 930; water-closets, 86.

"Before the improvement the meter registered (from December 20 to March 22) 2,771=32·4 gallons per head per day.

"After the improvement (from April 12 to June 26), 1,160,020=16·6 gallons per head per day."

In a subsequent letter, dated the 17th of this month (January 1867), Mr. Main writes:—

"I now subjoin particulars of a large district, consisting entirely of tenemented property where several tenants are supplied at one tap. You are aware how large a proportion of Newcastle consists of property of this description, and I was anxious to show you the results of our improvements in a district different from any of those previously given.

I may mention that the overhaul in this large district has been more thoroughly carried out than in any other.

"Diana Street and adjoining streets—number of inhabitants, 5,605; water-closets, 60.

"Consumption per head per day before improvements in water-closets and taps, 31 gallons; after improvements, 12 gallons."

The small consumption which generally prevails in the manufacturing towns of the north of England may, to a great extent, be owing to the custom which has commonly been adopted by the water companies and several of the corporations of doing their own plumbing work.

It is their interest to employ pipes of such strength and fittings of such approved construction, and to execute their work in such a manner as to prevent as far as possible all waste from leakage and bad taps. They do their plumbing, therefore, not for the purpose of carrying on a lucrative trade, but for securing thoroughly good materials a

workmanship, and the best results to all parties have followed.

Shortly after the introduction of a new and ample supply of water into Manchester in the year 1850, the old system of intermittent supply was superseded by that of the constant system; but it was only gradually introduced. The city was divided into small districts, and all means were taken for seeing that all the pipes and water-fittings were of the best description, and suitable for use under the constant supply system, before the inhabitants were allowed to enjoy that advantage. At my suggestion, the corporation in whose hands the water supply was, adopted the plan so successfully pursued in other towns of being their own plumbers, but the clamour and opposition of the plumbers of the city was too much for popular representation, and the system was gradually relaxed. They discontinued the plumbing, but they established a warehouse or shop for the sale of fittings, purchasing the very best, and, as far as possible, compelling the plumbers to purchase from them, allowing the adoption of none which were not approved.

After a time this was discontinued, and a certain number of plumbers were licensed, or authorized to do the requisite work on certain conditions—with which they were obliged to comply. These regulations are still continued, and there is probably no great water supply in the world, which is administered with as little waste and with as much convenience and comfort to the inhabitants.

It will be thus seen, that where everything is in good order, and both the water provider and the water consumer do their respective duties properly, there is no disadvantage to either party by the supply of water on the constant supply system—while the advantage to the consumer, in the facility with which he obtains water, and the trifling cost at which it can be introduced into his premises, are incomparably greater than can be enjoyed under the other system. Where, however, the intermittent system has hitherto prevailed, the desirableness, and, indeed, practicability of abandoning it, and adopting the constant supply, depends very much upon the consumers. If they will submit to such regulations as are necessary for preventing waste, there can be no difficulty in introducing constant supply—it will consume no more water than the intermittent system. The only changes which are required, are the abandonment of all bad fittings, such as common ground taps, leaky cocks, and wasteful waterclosets. The cisterns, already existing in houses which have been adapted to the system hitherto employed, may remain, if it be the will of the owner or occupier that they should. If they are large enough they do now practically give a constant supply, and it is only just to the provider of water, that care should be taken to prevent improper use. Those who prefer to abandon their cisterns and to take their water direct from the pipes, can do so at very little expense. In all new buildings there would be no necessity for the expensive paraphernalia of cisterns; a stopcock on the service pipe of the house would enable the water to be turned off whenever repairs or alterations were required to be made within the house. Little inconvenience is felt by grouping a number of houses together, commanded by one stopcock; and indeed, it may be said, that complaints of inconvenience arising from interruption to the supply of water, are scarcely ever heard in towns where the constant supply is at work. If the public will not submit to introduce the best description of fittings, and to prevent waste, and will not subject themselves to the vigilant inspection which ought to be exercised by the provider of the water, and be willing to correct everything which requires correction, it will be difficult and, in some cases, impossible to introduce the constant supply.

About 10 or 12 years ago, the city of Chester was supplied upon the constant system, after the inhabitants had been long accustomed to the intermittent. The company gave ample notice of their intention to change the system, and earnestly invited the inhabitants to co-operate with them in preventing waste. This call was not responded to by the consumers, and the result was that the consumption increased so much, that the pumping engines, which upon the intermittent system, were capable of affording all the supply required by working 12 hours a day, were compelled to work night and day, in order to supply what was required upon the constant system. The company were obliged in self-defence to return to the intermittent mode—on which the city is now supplied. This, however, is the only case of failure in my experience, and it may perhaps be accounted for by want of proper or resolute determination on the part of the company in bringing offenders to justice.

I must not omit, however, to notice the great consumption of water which obtains in many of the Scotch towns, and notably in the city of Glasgow. There, under both the intermittent and constant system, the quantity supplied has been enormous; but it is easily accounted for and might be remedied.

Under the old system of a partially-intermittent supply—when the water was pumped from the Clyde, the gross consumption was at the rate of 40 gallons per head per day, 36 gallons of this being due to domestic consumption and waste, the latter element being mainly chargeable with the extravagant consumption.

When re-arranging the piping for the reception of the water from Loch Katrine, I felt it important to draw the attention of the corporation to the large consumption, and to the growing habits of waste; and I cannot more clearly explain my views than by reading a portion of a report which I had occasion to make on the re-arrangement and extension of the city piping in February, 1858. In this report, after alluding to the state of things which existed, I say:—

"I will not enter into the question of whether 'constant supply' or 'intermittent supply,' as they have been respectively termed, is the best system for the supply of a town. It is your intention to give the inhabitants the full advantage of the Loch Katrine water constantly laid on, and from the elevation of the Mugdock reservoir, always at high pressure.

"The two systems have each been warmly advocated, but my observation and experience lead me to the conclusion that the 'constant system' when properly regulated, is much the most convenient on the whole—the least expensive to the tenant, and not more costly either in works or water than the other. It is no new or untried arrangement, as has been erroneously supposed, for it is the common mode in which most of the large manufacturing towns of the north of England have been supplied for the last 30 years.

"Where this system has always been the one adopted, or where it has been in existence for a considerable period, with everything in good order and under vigilant regulation, the consumption of water is, I believe, less than it would be in the same town under the intermittent system, supposing that in both cases an unstinted supply be given; but where a change has to be made from the 'intermittent' to the 'constant' system, very great waste is commonly the result, and it requires the utmost vigilance, and the most persevering attention, and, indeed, severity, to prevent it.

"Under the intermittent system people become negligent of the state of repair of their pipes and water fittings; they keep their taps constantly open, and are heedless about the waste which frequently takes place during the periods of the water being laid on. The water-works officials generally wink at this state of things, from a feeling that the waste only takes place within a limited area, and for a limited number of hours, and that it is effectually prevented during such periods as the water is wholly shut off.

"Should, however, the same state of things exist under a system of constant supply and at high pressure, the waste would be enormous, and even Loch Katrine would be found inadequate to meet it.

"In introducing the constant supply, therefore, where it has never been in use before the inhabitants should be previously prepared by due notice of the time at which it would be commenced, by imperative injunctions to put their pipes and taps into good order, and to abandon the use of all vessels for collecting or storing water, except those properly furnished with ballcocks. These injunctions should be followed by the most active supervision and by the most unmitigated severity of which the law admits, in all cases of neglect. By degrees the inhabitants would become accustomed to the new system, and after a time it would work harmoniously and advantageously for all the parties interested.

"These observations apply only partially to Glasgow, for in Gorbals, and over a large portion of the city north of the Clyde, the supply has for a long time been constant; but there are districts in which the intermittent system still prevails, and over the whole city the pressure and the consequent waste from bad fittings will be materially increased."

Then, with reference to the waste from water-closets, I say in the same report:

"Nothing can be a greater luxury than a well-kept water-closet perfect in all its parts and appurtenances, properly separated from the living rooms of a house; and in a rich man's residence, or in the hands of those who will spare no labour nor money to erect them first, and to maintain them afterwards in perfect efficiency, it is no doubt the

ne plus ultra of comfort, convenience, and cleanliness. But all who are in the habit of using them know how much trouble there is to keep them right, how frequently they go out of repair, and what a terrible nuisance it is when they do. Careless housemaids will put down mops or brushes, spoons or cinders, just as it may happen; working apparatus will get out of order, and soil pipes and drains will occasionally become stopped. These inconveniences, however, occurring to a man who can afford it, may be rectified by pains and money, and they do not amount in such case to an argument against the use of an arrangement which possesses so many counterbalancing recommendations and advantages. But change the scene to the house of the poor man, or to the dwelling of one who is careless of personal comfort, or perhaps of decency, and all these inconveniences become evils of very serious magnitude. There is seldom space enough properly to separate the water-closet from the apartments in which the family live, and if it gets out of order it will either be carelessly neglected, or it will cost money to repair which cannot be afforded. If the arrangement admits of it most likely the water will be kept constantly running, and the soil-pan open—the effect of which is to waste the water and to permit the free escape of all noxious effluvia from the drains and sewers into the ill-ventilated apartment in which the family resides. Nothing could be more perfectly contrived for poisoning the atmosphere and engendering disease. Nor is this all. The habits of the lower orders are such as to render a state of disrepair a thing of more common occurrence with them than amongst the upper classes. It is the readiest receptacle for anything that has to be thrown away, and the absence of toys and amusements amongst the unfortunate, cribbed and cabined children of the poor affords a strong temptation to resort to so capital a substitute as the plug of a water-closet, the unconscious little urchins never dreaming that on every repetition of their fun in opening and shutting the pan they allow the escape of poisoned air.

"The ordinary water-closet, under the best of circumstances, is generally productive of much waste of water, and if the cistern supplying it be also furnished with a waste-pipe, the water running away imperceptibly and uselessly may be very considerable.

"I would, therefore, respectfully beg your attention to this subject, both on account of the cost of the water and the health of the city, and urge you to institute very active supervision and the compulsory use of apparatus of the most approved construction, so as to reduce or remedy the evils I have pointed out. Many amongst the poorer classes are no doubt as careful to have everything in good order and as clean and sweet as their richer neighbours; but I apprehend this is not the ordinary rule, and much improvement must take place in the habits of the lower orders generally before these remarks are altogether inapplicable."

Then, as to cisterns :

"A further active agent in waste is the old system of cisterns, which is the necessary accompaniment of an intermittent supply, and which therefore prevails over the whole city—Gorbals to a great extent included—in consequence of the diminution of pressure in the pipes.

"The use of cisterns is, I believe, indispensable at present, and under any system of supply they are attended with so many advantages and conveniences, that it may frequently, perhaps generally, be desirable to retain them. Under constant supply, cisterns are not absolutely necessary, except to water-closets; but as they have the effect of lessening the pressure, the waste from bad taps and imperfect fittings is reduced by their use, if they themselves are properly fitted up with unexceptional ball-cocks to shut off the water when the cistern is full. If this is not attended to, the water which may pass off unperceived from the waste pipe of the cistern may be very considerable; and, as the cisterns are frequently placed on roofs and in other inaccessible places, they are not easily inspected and are never visited except in cases of necessity."

But one of the great causes of waste in Glasgow was the wretched character and condition of kitchen taps and the water-fittings generally. A rather startling account of these elements of waste was contained in a report prepared from careful observations and measurements made by Mr. James M. Gale, in Gorbals, in 1850, and on this report I made the following remarks :

"From these, it appears that the average daily waste by 135 families from badly constructed or imperfectly fitting kitchen taps alone, amounted to 108 gallons per family, or 20 gallons per head per day.

"In one staircase, while one careful man wasted nothing, another negligent fellow ran down his sink-stone, for no useful purpose to himself, no less than 850 gallons a-day.

"This waste is principally caused by the universal custom in Glasgow of using the common ground tap—the worst description of tap for water under pressure which can be adopted, and which has long since been exploded in all improved and well-regulated waterworks in England."

No great attention was paid to the workings which this report contained till after the introduction of the Loch Katrine water.

This took place at the close of 1859, and by March 1860, the whole city north of the Clyde was receiving this water. On the 6th of June, only three months later, I felt compelled to make the following report :—

"I must draw your attention to the present consumption of water, which is increasing so rapidly as to be really alarming, and quite warrants the apprehensions I felt, and the pains I took to guard you against it, when writing my report on the city piping in February, 1858. Referring then to the habits of waste which existed, and to the imperfect state of the water fittings, I observed that 'should the same state of things continue under a system 'of constant supply, and at high pressure, the waste would 'be enormous, and even Loch Katrine would be found 'inadequate to meet it.' At the time I wrote this, the consumption on the north side of the river was a little under 13,000,000 gallons a-day. In November last, 18 months later, it had increased to 14,000,000 and in the beginning of March of this year, after the whole of the city on this side was supplied with Loch Katrine water, it war 15,000,000 gallons per day. It has gone on increasing since then, till it now amounts to 18,000,000 gallons per day, being an increase of 3,000,000 gallons a day in three months. The consumption by the city was measured at the Mugdock Reservoir every hour for twenty-four hours consecutive, in the beginning of this week. The greatest draught is about 1 o'clock in the day, when it is at the rate of 22,000,000 gallons a-day, and the least at 2 o'clock in the morning when it amounts to about 14,000,000. At this time of the night, nearly the whole of this quantity must be wasted.

"The total consumption of the city from Loch Katrine and Gorbals together is 22,000,000 gallons a-day, being at the rate of about 50 gallons per head, and just twice in gross quantity as much as Manchester and Salford take for a larger population."

Upon this statement Mr. Gale, the resident engineer, was instructed to institute such an examination as would lead to the discovery of the cause of the excessive waste of water. He found that from badly-constructed and leaky taps alone the waste amounted to 7,200,000 gallons per day, equal to 20 gallons per head, the value of which, if sold for trade purposes, would have been about 50,000*l.* per annum.

What followed after this will be seen from a report I addressed to the Water Committee in January, 1862 :—

"I must again draw your attention to the rapid increase in the consumption of the water. The city on the south of the Clyde has exhausted its own supply from the Gorbals works, and is now assisted by a supply from Loch Katrine.

"The gradual increase in the city north of the Clyde has been as follows :—

"In the beginning of 1858, the daily consumption was 13,000,000 gallons. In November, 1859, just before the introduction of Loch Katrine water, it had risen to 15,000,000. In March, 1860, the whole of the city north of the Clyde was supplied from Loch Katrine, and by June the consumption from that source had arrived at 18,000,000 gallons per day.

"I then brought the subject prominently under your notice. Careful investigations into the causes of waste were made by Mr. Gale, by your directions. He found that no less than 7,200,000 gallons a-day were run to waste by leaky and bad taps alone, a quantity which he estimated at a money value of 50,000*l.* per annum. Stringent supervision was introduced, and other measures taken for remedying this enormous evil, and by October the quantity had been reduced to 13,000,000 gallons, being a saving of 5,000,000 gallons a-day in three months.

"At this point the consumption remained for a few months, but it is again steadily on the increase. At the commencement of 1861, it was in round numbers the same as it had been brought down to in October—viz., about 13,000,000 gallons a-day. It was maintained at this low point, to some extent, by so closing the valves as to reduce the pressure in the lower parts of the city to what was equivalent to only 70 feet in height, thus throwing away the advantage of high pressure, for the extinction of fires and for other purposes.

"By Midsummer the consumption had increased to 15,500,000 gallons. In August the Loch Katrine water was turned on to the west end of Gorbals, and in September the pressure in the pipes during the night was increased to about 140 feet. These arrangements, and a recurrence, no doubt, to the old habits of waste, brought up the consumption to upwards of 17,000,000 gallons per day, which added to the supply from the Gorbals works, made the total daily quantity supplied to the city 21,000,000 gallons, or 46⅔ gallons per head per day on the population of 450,000 who are supplied by the two works.

"Here is an increase in one year of 4,000,000 gallons per day."

There is a further report on this subject from Mr. Gale in November, 1864, giving the details of inspection and the then condition of the taps and water fittings. Special regulations had been established for the introduction of improved apparatus, but there still remained 41 per cent. of those in use which were not consistent with these regulations.

This case of Glasgow will no doubt be much relied upon by the opponents of the "constant supply system;" but the extravagant consumption is clearly due to causes which may be remedied, and to the fact that the Corporation have never resolutely and perseveringly set to work to apply the requisite remedies. The people of Glasgow look upon Loch Katrine as practically inexhaustible. The works are constructed on a scale for bringing more than twice the quantity now used. They are their own property, and as the water is supplied by gravitation, the excessive waste which takes place costs them nothing at present.

I see no reason to doubt that if in this great metropolis the providers of water and the consumers of water will each do their duty and work harmoniously together, the citizens may enjoy the inestimable benefit of an unlimited supply of water, constantly laid on, without consuming a gallon more water, if indeed as much as is now supplied by the water companies.

APPENDIX K.

MEMORANDA of the Cost of PUMPING and FILTRATION.

Southwark and Vauxhall Water Company,
Office, Sumner Street, Southwark, S.E.

MY DEAR SIR, 27th February 1868.

I FIND the cost of raising 1,000 gallons of water by this company, 100 feet high, is between $\frac{1}{6}$ and $\frac{1}{7}$ of a penny, or 13*s.* 10*d.* per 1,000,000 gallons, including coals, oil, and tallow, wear and tear, &c.

Yours very truly,
JOSEPH QUICK.

T. Harrison, Esq., C.E.

Southwark and Vauxhall Water Company,
Engineers' Office,
Sumner Street, Southwark,

SIR, 20th March 1868.

IN reply to the question contained in your letter of the 11th inst. as to the cost of pumping water by this company to a height of 100 feet, I beg to state that the sum named included the expense of coals, oil, tallow, labour, and ordinary repairs.

The cost of filtering water, including labour, scraping, cleansing, and renewing sand is $\frac{1}{14}d.$ (one fourteenth of a penny) per 1,000 gallons, exclusive of interest on capital.

I am, &c.
JOSEPH QUICK.

Dr. Pole, &c. &c.

29, Great George Street, Westminster, S.W.

DEAR SIR, 24th March 1868.

IN reply to your inquiry I estimate the cost of pumping per million gallons 100 feet high at 1*l.* 0*s.* 3*d.*, including coals, tallow, oil, and other stores, labour, repairs, &c.

And the cost of filtering at 5*s.* 4*d.* per million gallons, including labour, cleaning, and sand for renewal.

I am, &c.,
JAMES SIMPSON.

Wm. Pole, Esq.

APPENDIX L.

RETURNS as to the CAPABILITIES of the METROPOLITAN WATERWORKS, drawing Water from the Thames, for increasing the Quantity of Water taken.

The following letter was written to each company.

11th March 1868.

I AM desired by this Commission to ask the favour of your informing them,—

Whether the works of the Company are calculated to take from the Thames a larger quantity than at present? and if so, what is the maximum daily quantity you could pump, filter, and deliver into your distributing reservoirs, without materially adding to your present capital?

Any further outlay necessary for increased storage and distribution need not be considered.

I am, &c.
(Signed) WILLIAM POLE, Secretary.

To this letter the following answers were returned.

29, Great George Street, Westminster,

SIR, S.W., 24th March 1868.

IN reply to your letter of 11th instant, I beg to state that the Chelsea Company's works were originally laid out for 40,000,000 gallons per diem, and with the works now in action and in progress are calculated to take from the Thames a larger quantity of water than at present, and without materially adding to the present capital the company's works could pump, filter, and deliver into the distributing reservoir 20,000,000 gallons per diem.

I am, &c.,
JAMES SIMPSON.

Wm. Pole, Esq., Secretary,
Royal Commission on Water Supply.

Office of West Middlesex Waterworks,
19, Marylebone Road, W.,

SIR, 19th March 1868.

IN reply to your letter of the 11th instant, inquiring whether the works of the West Middlesex Company are calculated to take from the Thames a larger quantity of water than at present, and if so, what is the maximum daily quantity that we could pump, filter, and deliver into our distributing reservoirs without materially adding to our present capital, and stating also that any further outlay for increased storage and distribution need not be considered, I am desired to inform you that the company is authorized

to take 20,000,000 gallons dailyfrom the Thames, and that our present works at Hampton can, without any increase of capital, pump about 12,000,000 gallons per day. The filter beds at Barnes will yield about 16,000,000 gallons per day, and the engines at Hammersmith will deliver into the district and distributing reservoirs about 14,500,000 gallons per day.

I am desired to add that the average daily supply of the company is about 8,500,000 gallons, and that the present works are considered to be sufficiently ahead of all existing demands.

I am, &c.,
W. H. Whiffin,
Secretary.

To the Secretary, &c.,
Royal Commission on Water Supply,
Committee Room F., House of Lords.

Sumner St., Southwark,
20th March 1688.

Sir,

In reply to your letter of the 11th inst., I beg to inform you that the Grand Junction Water Company have power to take 20,000,000 gallons of water per day into their reservoirs at Hampton, in accordance with their arrangements with the Thames Conservancy Board.

The maximum quantity that could be delivered through the 33-inch main to the works of distribution at Kew Bridge is 13,000,000 gallons in 24 hours.

The reservoirs, filtering beds, and engine power at the Kew Bridge and Campden Hill Works are capable of filtering and delivering this quantity (13,000,000 gallons) to the district in 24 hours.

Reserve engine power, filtering beds, &c. are provided in case of accident, for repairs, cleansing, &c.

The Company have also recently purchased land at Campden Hill, on which it is intended to construct additional works to meet the increasing requirements of their district, and to prevent the present works being tasked beyond their safe working power. The estimated outlay for this and some additions to the Kew Bridge and Hampton Works will amount to at least 140,000*l*.

I am, &c.,
Joseph Quick.

Dr. Pole, &c.,
Royal Commission on Water Supply.

Office of Lambeth Water Works,
175, Kennington Park Road, S.
25th March, 1868.

Sir,

Your letter of the 11th inst., addressed to Mr. Simpson, the Company's engineer, having been laid before the directors of Lambeth Water Works, I am desired by them in reply to acquaint you, for the information of the Royal Commission on Water Supply, that the works of this Company are calculated to take from the River Thames, filter, pump, and deliver the same into the distributary reservoirs, 20,000,000 gallons of water per diem, without materially adding to the present capital.

And I am to state that the works as originally designed were calculated for 40,000,000 per diem, and the land as a pipe track for four large mains to supply that quantity of water was purchased for that purpose soon after the Company's Act of Parliament was obtained.

I am, &c.,
W. S. Phipps,
Secretary.

William Pole, Esq.
Secretary.

Sumner Street, Southwark,
20th March, 1868.

Sir,

In reply to your letter of the 11th inst. I beg to inform you that the Southwark and Vauxhall Water Company have power to take 20,000,000 gallons of water per day into their reservoirs at Hampton in accordance with their arrangements with the Thames Conservancy Board.

The maximum quantity that could be delivered through the 36-inch main to the works of distribution at Battersea is 15,000,000 gallons in 24 hours.

The reservoirs, filtering beds, and engine power at the Battersea works are capable of filtering and delivering this quantity (15,000,000 gallons) to the district in 24 hours.

Reserve engine power, filters, &c., are provided in case of accident, for repairs, cleansing &c.

The Company have also purchased land, and are constructing additional works at Hampton, and laying down a new line of 30-inch main to supply the Western portion of this district. The outlay for this and some additions required to the Battersea works will amount to at least 150,000*l*.

I am, &c.,
Joseph Quick.

Dr. Pole, &c., &c.
Royal Commission on Water Supply.

APPENDIX M.

DETAILS furnished by Mr. BATEMAN in illustration of his EVIDENCE.

No. 1. PARTICULARS of ESTIMATE of Mr. BATEMAN'S Scheme for obtaining a Supply of Water from NORTH WALES of 230,000,000 gallons daily.—Revised December 1867.

RESERVOIRS and WORKS of COLLECTION and BRANCH AQUEDUCTS to MARTEN MERE.

Rivers Vyrnwy and Banw District.

Vyrnwy District.			
Reservoir at Llanwddyn:—			
Embankment 76 ft. high, capacity, with 70 feet depth of water at embankment, 1,490,000,000 cubic feet:—			
Earthwork 186,000 cubic yards, at 1*s.* 6*d.*	£13,950		
Tunnel, discharge pipes, and valves, 150 lineal yards, at 50*l.*	7,500		
Waste weir, valve houses, &c.	5,000		
Fencing 10 miles at 200*l.* per mile	2,000		
	£28,450		
Diversion of roads, to include bridges, culverts, drains, fencing, &c.:—			
Six miles at 2,200*l.* per mile	£13,200		
Three miles at 880*l.* per mile	2,640		
	15,840		
		£44,290	
Diversion of flood water of the Afon Conwy to Llanwddyn reservoir.—Drainage area, 3,016 acres.			
Open watercourse, 2,200 lineal yards at 2*l.*	£4,400		
Tunnel, 1,320 lineal yards at 10*l.*	13,200		
	17,600		
			£61,890
Diversion of the river Vyrnwy at Pont Hagel to reservoir at Rhyd e Gro.			
Flood waters from 10,879 acres to be diverted, quantity provided for, 2,000 cubic feet per second.			
Weir across river Vyrnwy at point of diversion	£7,000		
Open watercourse (for detailed estimate and section, see Appendix A Q (1) 3,740 lineal yards at 11*l.*	£41,140		
Bridges, drains, &c.	3,000		
	44,140		
Tunnel (for detailed estimate and section, see Appendix A Q (2) 1,100 lineal yards, at 22*l.*	24,200		
		75,340	
			£137,230
Banw District.			
Reservoir at Can office. Embankment 80 feet high. Capacity, with 75 feet depth of water at embankment, 767,171,800 cubic feet.			
Earthwork, 300,000 cubic yards at 1*s.* 6*d.*	£22,500		
Discharge tunnel, pipes, valves, 150 lineal yards at 50*l.*	7,500		
Waste weir and valve houses	3,000		
Fencing six miles, at 200*l.*	1,200		
	£34,200		
Amount carried forward		£34,200	

Reservoirs and Works of Collection, &c.—*continued.*			
Rivers Vyrnwy and Banw District—*continued.*			
Banw District—*continued.*			
Amount brought forward		£34,200	
Diversion of roads, including bridges, culverts, drains, fencing, &c.			
3½ miles at 2,500*l.* per mile	£8,750		
2 miles at 1,320*l.* per mile	2,640		
	£11,390		
		£45,590	
Reservoir at Rhyd e Gro. Embankment 80 feet high. Capacity, with 75 feet depth of water at embankment, 974,636,900 cubic feet.			
Earthwork, 406,000 cubic yards, at 1*s.* 6*d.*	£30,450		
Discharge tunnel, pipes, valves, &c., 150 lineal yards, at 50*l.*	7,500		
Waste weir, valve houses, &c.	5,000		
Fencing, 7 miles, at 200*l.*	1,400		
	£43,350		
Road diversions, including bridges, culverts, drains, fencing, &c., 1 mile at 2,500*l.* £2,500			
3 miles at 1,320*l.* 3.960	6,460		
		£49,810	
Reservoir at Nant y eira. Embankment 80 feet high. Capacity, with 75 feet depth of water at embankment, 261,360,000 cubic feet.			
Earthwork, 97,000 cubic yards, at 2*s.*	£9,700		
Discharge tunnel, pipes, valves, &c.	4,000		
Waste weir, valve houses, &c.	4,000		
Fencing, 3½ miles at 200*l.*	700		
	£18,400		
Road diversions, odd prices	1,000		
		£19,400	
Flood watercourse from the upper end of the Nant y eira reservoir to the Can office reservoir to take surplus water; 3 miles, at 7,040*l.* per mile, including bridges, culverts, &c.	21,120		
		£135,920	
			£273,150
Branch aqueduct from Rhyd e Gro to Marten Mere. Open watercourse (for detailed estimate and section, see Appendix A Q (3); 5 miles, at 20,100*l.* per mile		100,500	
Covered watercourse, or tunnel (for detailed estimate and section, see Appendix A Q (4); 12 miles, at 26,100*l.* per mile		313,200	
Syphon across the valley of the Severn near Berriew (for detailed estimate, see Appendix A Q (5): 5 lines of 4 feet pipes; 2 miles, at 54,120*l.* per mile	£108,240		
Valves, wells, and crossing of river	5,000		
		113,240	
			526,940
Amount carried forward			£800,090

Reservoirs and Works of Collection, &c.—*continued.*

Rivers Vyrnwy and Banw District—*continued.*

Amount brought forward -		800,090
Banw District—*continued.*		
Amount brought forward - - -		
Contingencies:—15 per cent. on all works, except piping -	£686,850 =	103,027
5 per cent. on piping -	113,240 =	5,662
		108,689
Land for reservoirs, watercourses, and aqueducts, including rebuilding of church and village, and compensation - - - -		180,240
Total cost of Vyrnwy and Banw district branch of scheme, down to junction with main aqueduct at Marten Mere, capable of supplying to the city 130,000,000 gallons daily - - - - - - - -		£1,089,019

River Severn proper District.

Reservoir on the river Clwyedog. Embankment 70 feet high; capacity, with 65 feet depth of water at embankment, 203,056,522 cubic feet.			
Earthwork, 144,000 cubic yards, at 1*s.* 6*d.* - - -	£10,800		
Discharge tunnel, pipes, valves, &c., 130 lineal yards, at 40*l.* - -	5,200		
Waste weir, valve houses, &c. - - - -	2,500		
Fencing, 4½ miles, at 200*l.*	900		
	£18,400		
Diversion of roads, including bridges, culverts, drains, fencing, &c., 1 mile at 2,500*l.*	£2,500		
1½ mile at 880*l.*	1,320	3,820	
			£22,220
Reservoirs on the river Dulas and other streams south of the Severn; sites not surveyed; capacity required, 216,807,000 cubic feet. Estimate assumed to be the same as for the reservoir and accessory works on the river Clwyedog, £22,220 say - - - - -			25,000
Reservoir at Trefeglws on the rivers Ceryst and Tarannon.—Embankment 76 feet high; capacity, with 70 feet depth of water at embankment, 2,794,717,000 cubic feet.			
Earthwork, 1,620,000 cubic yards, at 1*s.* 2*d.*	£94,500		
Discharge tunnels, pipes, valves, &c., 300 lineal yards, at 50*l.* - -	15,000

TABLE A.

Table showing the probable Proportion of the first Instalment of 130,000,000 gallons per day required by each Company's District.

—	Present supply (1866).	Proportionate addition.	Estimated requirements in 1875 or 1876.
New River - -	23,000,000	5,600,000	28,600,000
East London -	19,300,000	7,300,000	26,600,000
Chelsea - -	8,000,000	1,150,000	9,150,000
West Middlesex -	8,250,000	4,350,000	12,600,000
Grand Junction -	8,700,000	4,600,000	13,300,000
Southwark and Vauxhall.	12,700,000	6,700,000	19,400,000
Lambeth - -	9,000,000	2,250,000	11,250,000
Kent - -	6,050,000	3,050,000	9,100,000
	95,000,000	35,000,000	130,000,000

It is proposed to form the metropolis into four districts, each communicating independently with the reservoirs at Edgware. These districts are,—

	Gallons daily.
No. 1. New River, supply required - -	28,600,000
East London, „ „ - -	26,600,000
	55,200,000
No. 2. Chelsea, supply required -	9,150,000
West Middlesex, „ „ -	12,600,000
Grand Junction „ „ -	13,300,000
	35,050,000
No. 3. Higher parts of the Lambeth and Southwark and Vauxhall districts, supply required, estimated at - - -	10,000,000
Kent district, supply required - -	9,100,000
	19,100,000
No. 4. Lower parts of the Lambeth and Southwark and Vauxhall districts - -	20,650,000

Level of top water of proposed service reservoirs near Edgware will be 270 feet above ordnance datum, or 257½ feet above Trinity high-water mark.

District No. 1.

The water will be conveyed to this district by a covered aqueduct commencing at the service reservoirs, at the level of 250 feet above ordnance datum at least, and terminating near Crouch End. From the end of the aqueduct the water will be conveyed by main pipes to the Maiden Lane reservoirs of the New River Company for their district, and to the new Hornsey reservoir and Lea Bridge for the supply of the East London district.

Aqueduct will be of the same size as the Loch Katrine aqueduct, with a fall of 14 inches per mile; the discharge will be as follows:—

Area, 49·317 square feet; wetted sides, 20·65 feet; mean velocity, 2·15 feet per second; discharge, 57,088,000 gallons per day.

Length of aqueduct, 7 miles, at 7*l.* per lineal yard - - - - - - - - -	£86,240
(This estimate is the average amount paid for the Duntreath section of the Loch Katrine aqueduct, which included 4 tunnels and 8 aqueducts, besides stream crossings, drains, &c. The amount of the final certificate, including all extras, was 61,769*l.*, and the length of the aqueduct was 8,888 lineal yards, or rather less than 7*l.* per lineal yard.)	
Contingencies, 10 per cent. - - - -	8,624
Land - - - - - - - - -	10,000
	£104,864

Level of aqueduct at the commencement, 250 feet above ordnance datum.

Level of ditto at its termination, 7 miles, at 14 inches fall per mile, 241 feet 10 inches above ditto.

Level of Maiden Lane reservoirs, 231 ft. 6 in. above ditto.

Level of New Hornsey reservoir, 140 ft. above ditto.

Level of Lea Bridge works, about 20 ft. above ditto.

	Distance.
Fall from termination of aqueduct to Maiden Lane, 10 ft. 4 in. - - - - - -	1½ mile.
Fall from ditto to New Hornsey reservoir, 101 ft. 10 in. - - - - - - -	1½ mile.
Fall from ditto to Lea Bridge, 221 ft. 10 in. -	4½ miles.

	Gallons per day.
Quantity to be delivered into Maiden Lane reservoir for New River district - -	28,600,000
Quantity to be delivered into New Hornsey reservoir, or to existing mains at Lea Bridge	26,600,000
New River supply.	
4 ft. pipe, with 7 ft. fall per mile, will deliver, according to calculation - - - -	23,516,000
Add 25 per cent. for actual over theoretical discharge - - - - - - -	5,879,000
Total -	29,095,000

No. 1.

East London supply. 4 ft. pipe with 7 ft. fall per mile, will deliver same quantity into New Hornsey reservoirs, or into existing mains at Lea Bridge, with a pressure at the latter place of about 190 feet.

Estimate:—One 4 ft. pipe to Maiden Lane reservoirs, 1½ miles in length; thickness, 1 in.; weight per yard, 14½ cwt. at 6*l.* per ton	14½ cwt. £4 7	
Laying and jointing	0 15	
Per lineal yard	£5 2	
2,640 lineal yards at 5*l.* 2*s.*		£13,464
1 4 ft. pipe to New Hornsey reservoir, and thence to Lea Bridge. Length, 4½ miles; thickness, 1⅜ in. on the average; weight per lineal yard, 20 cwt.	20 cwt. at 6*l.* per ton £6 0	
Laying and jointing	0 15	
	£6 15	
7,920 lineal yards at 6*l.* 15*s.*		53,460
		£66,924
Contingencies. 5 per cent. on piping		3,346
		£70,270

The existing service reservoirs of the New River Company will be sufficient for their district.

For the East London district it will be desirable to add to their new service reservoir at Hornsey, or construct others to hold half a day's supply, or about 14,000,000 gallons. The estimated capacity of the new Hornsey reservoir is 4,500,000 gallons; deficiency, 9,500,000 gallons — say 10,000,000 gallons.

District No. 2.

The water will be conveyed to this district by a 4 ft. pipe from the service reservoirs at Edgware, which will communicate with the West Middlesex main from Campden Hill to Barrow Hill, and be continued into the Grand Junction district to join their high district main, and so to the reservoirs on Campden Hill. From these reservoirs a main of 3 ft. diameter will be laid to communicate with the leading mains of the Chelsea district.

Pipe will leave reservoirs under pressure from a height of 270 feet above ordnance datum when the reservoir is full; but assume for calculations 262 feet 6 inches above ordnance datum (or 250 feet above Trinity high-water mark).

Existing Service Reservoirs.	Elevation above ordnance datum.	Capacity, gallons.
Notting Hill, West Middlesex	124 ft. 6 in.	3,672,000
Campden Hill, Grand Junction	132 ft. 6 in.	6,000,000
Barrow Hill, West Middlesex	190 ft.	4,750,000
Kidderpore do.	321 ft. 6 in.	2,500,000
		16,922,000

Quantity required for the whole district, 35,050,000 gallons daily.

Difference in level between reservoirs at Stanmore and mean elevation of reservoirs at Campden Hill and Barrow Hill (say 160 feet above ordnance datum on average), 262′ 6″—160″=102½ feet.

Distance from Edgware to Campden Hill, 10½ miles.

Fall equal about 9¾ feet per mile.

	Gallons.
4 ft. pipe, fall 9¾ feet per mile, will discharge	28,250,000
Add 25 per cent. for actual over theoretical discharge	7,062,500
	35,312,500

Estimate.

One 4 ft. main from Edgware to point of intersection with main from Campden Hill to Barrow Hill, 8½ miles, and thence to communicate with high-service main of Grand Junction district, 1½ miles; total 10 miles, at 10,000*l.* per mile		£100,000
One 3 ft. main from Campden Hill reservoir to intersect main lines of pipes to Chelsea district; 2 miles at 6,500*l.* per mile		13,000
		£113,000
Contingencies, 5 per cent.		5,650
		£118,650

District No. 3.

The water will be conveyed to this district by a 4 ft. main, crossing the Thames near Vauxhall Bridge by a special aqueduct; the 4 ft. pipe will then branch into two 36 in. pipes—one to the Streatham reservoir of the Lambeth Company, for the supply of the higher parts of that and the Southwark and Vauxhall Company's district; the other to new reservoirs to be made in or near Greenwich Park or Blackheath.

Service reservoir at Streatham Hill, 197 feet 6 inches above ordnance datum, to be enlarged so as to hold 5,000,000 gallons.

Distance from Edgware reservoirs to Streatham, 16 miles.

Service reservoir to be constructed at Greenwich at a level of about 160 feet ordnance datum, and to have a capacity of about 5,000,000 gallons.

Distance from Edgware reservoirs to Blackheath, 17½ miles.

Quantity required for—

	Gallons daily
Kent district	9,100,000
Lambeth high districts	5,000,000
Southwark and Vauxhall ditto	5,000,000
	10,000,000

Distance from Edgware reservoirs to south side of Vauxhall Bridge, 12 miles.

Difference of level between Edgware and—

Streatham, 262 ft. 6 in.:—197 ft. 6 in. = 65 ft., or 4 ft. fall per mile.

Blackheath, 262 ft. 6 in.:—160 ft.=102 ft. 6 in., or 6 ft. fall per mile.

	Gallons daily.
3 ft. pipe to Streatham, with 4 ft. fall per mile, will deliver	8,351,000
Add 25 per cent. for actual over theoretical discharge	2,087,750
	10,438,750
3 ft. pipe to Blackheath; fall 6 feet per mile	10,470,000
Add 25 per cent., as above	2,617,500
	13,087,500
Total capability of 3 ft. pipes	23,526,250

Estimate:—4-ft. pipe from Edgware to south side of Vauxhall Bridge, 12 miles, at 10,000*l.* per mile		£120,000
3 ft. pipe to Streatham, 4 miles, at 6,500*l.*		26,000
3 ft. pipe to Blackheath, 5½ miles, at 6,500*l.*		35,750
		181,750
Contingencies, 5 per cent.		9,088
		190,838
Bridge over Thames, near Vauxhall Bridge, to carry three lines of 4 feet pipes		50,000
		£240,838

District No. 4.

It is proposed to lay down a 48-in. main from Edgware to the existing service reservoirs at Putney Heath of the Chelsea Water Company, and to use them for distributing to the lower districts of the Lambeth and Southwark and Vauxhall Companies.

The elevation of the reservoirs at Putney is 172 ft. 6 in. above ordnance datum.

The distance from Edgware is 15½ miles, and the difference of level is 90 feet, or nearly 6 feet fall per mile.

	Gallons daily.
One 4 ft. pipe with 6 ft. fall per mile will deliver	21,653,000
Add 25 per cent. for actual over theoretical discharge	5,413,250
	27,066,250
Quantity required for this district	20,650,000

Estimate:—15½ miles of 4 ft. pipes, at 10,000*l.* per mile		£155,000
Contingencies, 5 per cent.		7,750
		£162,750

No. 1.

WELSH SCHEME.—2nd Instalment.

Estimate of additional outlay required to increase the supply to 170,000,000 gallons daily, and of the cost to be incurred in distributing the additional quantity (40,000,000) to the several districts of supply.

Works in Wales and on main aqueduct to Edgware.

Reservoirs and works of collection of the river Severn proper branch of the scheme, and branch aqueduct to Marten Mere, as per estimate, see p. 2.		£1,062,408
Syphons. Two additional lines of 4 ft. pipes on line of main aqueduct to Edgware, 11½ miles, at 21,648*l.*	£248,952	
Valves and river crossings (3)	5,000	
	£253,952	
Contingencies, 5 per cent.	12,698	
		266,650
		1,329,058
Additional service reservoir at Edgware, and works for distributing additional quantity of 40,000,000 gallons daily, (for particulars, see pp. 5 and 6.)		557,551
		£1,886,609

TABLE showing the probable Proportion of the whole Supply, when it amounts to 170,000,000 gallons daily, required by each Company's District.

	First Instalment.	2nd Instalment of 40,000,000 gallons additional.	Total.
New River Co. -	28,600,000	8,580,000	37,180,000
East London -	26,600,000	7,980,000	34,580,000
Chelsea - -	9,150,000	2,835,000	11,985,000
West Middlesex -	12,600,000	3,780,000	16,380,000
Grand Junction -	13,300,000	3,990,000	17,290,000
Southwark and Vauxhall.	19,400,000	5,820,000	25,220,000
Lambeth - -	11,250,000	3,375,000	14,625,000
Kent - -	9,100,000	3,640,000	12,740,000
	130,000,000	40,000,000	170,000,000

		Gallons.	Gallons.
District No. 1.	New River -	37,180,000	
	East London	34,580,000	
			71,760,000
District No. 2.	Chelsea - -	11,985,000	
	West Middlesex -	16,380,000	
	Grand Junction -	17,290,000	
			45,655,000
„ „ 3.	Higher parts of Lambeth district - -	8,000,000	
	Southwark and Vauxhall -	8,000,000	
		16,000,000	
	Kent - - -	12,740,000	
			28,740,000
„ „ 4.	Lower parts of Lambeth district - -	6,625,000	
	Southwark and Vauxhall -	17,220,000	
			23,845,000
			170,000,000

District No. 1.

Total supply - - -	71,760,000	gallons daily.
Supply under 1st instalment -	55,200,000	„ „
Additional quantity - -	16,560,000	„ „

It will be necessary to make another aqueduct from the reservoirs at Edgware to near Crouch End, and lay an additional pipe from thence to the New River reservoirs at Maiden Lane for the additional quantity required for that district, viz., 8,580,000 gallons daily.

The 4-ft. pipe to the proposed service reservoirs of the East London district, and to the Lea Bridge mains, provided for the distribution of the 1st instalment, will deliver the additional quantity of 7,980,000 gallons required for this district, with an extra fall of 3 feet per mile, reducing the effective pressure at Lea Bridge from 190 feet to about 175 feet.

Additional service reservoirs, to the extent of about 4,000,000 gallons, will be required for the East London district.

Estimate.

Aqueduct from Edgware to Crouch End, same dimensions, as before - - -		£104,864
1 4-ft. pipe to Maiden Lane reservoirs - - - - -	£13,464	
5 per cent. for contingencies - -	673	
		14,137
		£119,001

District No. 2.

Total supply - - -	45,655,000	gallons daily.
Supply under 1st instalment -	35,050,000	„ „
Additional quantity - -	10,605,000	„ „

It will be necessary to lay an additional main from Edgware for the supply of this district, and looking to future wants, it would be well to provide for an additional 4-ft. pipe all the way through the higher parts of the Paddington district to Campden Hill, a distance of 10½ miles. The actual discharge of this pipe, with a fall of 12½ feet per mile, will be, at the level of Campden Hill, 132½ feet above ordnance datum, about 40,000,000 gallons in 24 hours.

Additional service reservoirs, to the extent of about 6,000,000 gallons, will also be required in this district.

Estimate.

One 4-ft. pipe from Edgware to Campden Hill, 10½ miles at 1,000*l.* per mile - - -	£105,000
Contingencies, per cent. - - - -	5,250
	£110,250

District No. 3.

Total quantity required,	28,740,000	gallons daily.
Supply under 1st instalment,	19,100,000	„ „
Additional supply	9,640,000	gallons daily.

Of this additional quantity, 3,640,000 gallons are for the Kent district, and 6,000,000 for the higher parts of the Lambeth and Vauxhall districts.

The pipe provided for the 1st instalment to the Kent districts will be sufficient to deliver the whole quantity now estimated to be there required, viz., 12,740,000 gallons per day.

For the higher parts of the Lambeth and Southwark and Vauxhall districts it will be necessary to lay additional pipes, and looking to the future requirements of the district it is desirable to lay a new 4-ft. main from Edgware to the south side of Vauxhall Bridge, and a 3-foot pipe thence to the proposed service reservoirs at Streatham.

Additional service reservoirs for the Kent and higher parts of the Lambeth and Southwark and Vauxhall districts will be required to the extent of 5,000,000 gallons.

Estimate.

One 4-ft. pipe from Edgware to south side of Vauxhall Bridge, 12 miles at 10,000*l.* per mile - - - - - - - -	£120,000
1 3-ft. pipe from thence to Streatham, 4 miles, at 6,500*l.* - - - - - - -	26,000
	£146,000
Contingencies, 5 per cent. - -	7,300
	£153,300

No. 1. Welsh Scheme—2nd Instalment—*continued.*

No. 4 District.

Total supply - - -	23,845,000 gallons daily.
Supply under 1st instalment	20,650,000 „ „
Additional quantity	3,195,000

The 4-ft pipe laid down for the first instalment will be sufficient for the additional quantity.

Summary of estimate for additional reservoir at Edgware, and for additional aqueduct and main pipes to communicate with existing distribution arrangements for delivering a total supply of 170,000,000 gallons per day.

Service reservoir at Edgware, including land and contingencies, say - - - -	£100,000
District No. 1—Aqueduct to Hornsey and main to Maiden Lane reservoirs - -	119,000
District No. 2. Mains - - - -	110,250

Welsh Scheme.—3rd Instalment—*continued.* No. 1

			Gallons.
Brought forward - - -			137,415,000
District No. 3.	Higher parts of Lambeth district	10,500,000	
	Southwark and Vauxhall - -	10,000,000	
		20,500,000	
	Kent - -	16,240,000	
			36,740,000
„ 4.	Lower parts of Lambeth district	6,625,000	
	Southwark and Vauxhall - -	19,220,000	
			25,845,000
			200,000,000

District No. 1.

	Gallons daily.
Total supply - - - - - - -	84,260,000
Supply under 1st and 2nd instalments -	71,760,000
Additional quantity - - - -	12,500,000

The aqueducts already provided for will deliver more than the total quantity required, and the pipes to Maiden Lane reservoirs will supply more than the additional quantity required for the New River district.

The 4-ft. pipe to the proposed service reservoirs of the East London district and to Lea Bridge, already provided for in the estimates, will deliver the additional quantity of 6,000,000 gallons required for this district, with an extra fall of 3 feet per mile, reducing the effective pressure at Lea Bridge to about 160 feet.

No additional outlay will be required for this district, except for service reservoirs to the extent of 6,000,000 gallons.

District No. 2.

	Gallons daily.
Total supply - - - - - -	53,155,000
Supply under 1st and 2nd instalments - -	45,655,000
Additional quantity - - - - -	7,500,000

The mains already estimated for for this district are much more than equal to the delivery of the additional supply. No outlay is consequently necessary for this district, except for additional service reservoirs to the extent of about 4,000,000 gallons.

District No. 3.

Total supply - - - - - - -	36,740,000
Supply under 1st and 2nd instalments - -	28,740,000
Additional quantity - - - - -	8,000,000

3,500,000 gallons additional are for the Kent district, and 4,500,000 gallons for the higher parts of the Lambeth and Southwark and Vauxhall districts.

The 4-ft. mains to be laid from Edgware to the south side of Vauxhall Bridge, already estimated for, are more than sufficient for the whole district, but an additional 3-ft. pipe will be required for the Kent district. The pipes to the Streatham proposed service reservoirs are equal to the additional supply.

Additional service reservoirs to the extent (4,000,000) gallons will be required for the district.

Estimate.

5½ miles of 3-ft. pipe to Blackheath, at 6,500*l.* per mile - - - - - - - -	£35,750
Contingencies, 5 per cent. - - - -	1,785
	£37,535

District No. 4.

	Gallons daily.
Total supply - - - - - -	25,845,000
Supply under 1st and 2nd instalments -	23,845,000
Additional supply - - - - -	2,000,000

The main already provided is equal to the delivery of this additional quantity; no outlay is consequently required in this district, except for service reservoirs to the extent of say 2,000,000 gallons.

No. 1. Welsh Scheme—3rd Instalment—*continued.*

Summary of outlay to be incurred in distributing the additional 30,000,000 gallons daily, increasing the total supply to 200,000,000 gallons daily:—

District No. 3—Main	£37,535
Additional service reservoirs:—	
District No. 1 - 6,000,000 gallons.	
„ „ 2 - 4,000,000 „	
„ „ 3 - 4,000,000 „	
„ „ 4 - 2,000,000 „	
16,000,000 gallons.	
16,000,000 gallons, at 5,000*l.* per million -	80,000
	£117,535

Welsh Scheme.—4th Instalment.

Estimate of cost to be incurred to increase the supply to 230,000,000 gallons daily, and for distributing the additional 30,000,000 gallons daily to the several districts:—

Syphon on line of main aqueduct to Edgware, 1 line of 4-ft. pipes, 11½ miles at 10,824*l.*	£124,476	
Valves and river crossings (3)	2,500	
	£126,976	
Contingencies, 5 per cent.	6,348	
		£133,324
Additional service reservoir at Edgware, and mains and district service reservoirs (see page 7)		444,225
		£577,549

Table showing the probable Proportion of the whole Supply, when it amounts to 230,000,000 gallons daily, required in each Company's District.

			28,845,000
			230,000,000

District No. 1.

	Gallons daily.
Total supply	96,760,000
Supply under 1st, 2nd and 3rd instalments	84,260,000
Additional quantity	12,500,000

Welsh Scheme—4th Instalment—*continued.*

The aqueducts and mains already provided for this district are equal to the supply of the additional quantity, but the effective pressure at Lea Bridge will be reduced to about 150 feet. No outlay is required for this district except for additional service reservoirs to the extent of 6,500,000 gallons.

District No. 2.

	Gallons daily.
Total supply	60,655,000
Supply under previous instalments	53,155,000
Additional supply	7,500,000

The mains provided for this district are more than sufficient for the additional supply, but new service reservoirs, to the extent of 3,500,000 gallons, will be required.

District No. 3.

	Gallons daily.
Total supply	43,740,000
Supply under previous instalments	36,740,000
Additional quantity	7,000,000

Of which 3,000,000 are for the Kent district, and 4,000,000 for the higher parts of the Lambeth and Southwark and Vauxhall districts.

The mains already laid to the Kent district are more than sufficient for the delivery of the new supply.

For the higher parts of the Lambeth and Vauxhall an additional main from Edgware will be necessary, and additional service reservoirs to the extent of 3,500,000 gallons will be required for the whole district.

Estimate:—

4-feet pipe from Edgware to south side of Vauxhall Bridge, 12 miles, at 10,000*l.* per mile	£120,000
3-feet pipe to Streatham, 4 miles, at 6,500*l.* per mile	26,000
	£146,000
Contingencies, 5 per cent.	7,300
	£153,300

District No. 4.

	Gallons daily.
Total supply	28,845,000
Supply under previous instalments	25,845,000
Additional supply	3,000,000

It will be necessary to lay an additional main from Edgware to the reservoirs on Putney Heath, say 3 feet diameter.

3-ft. pipe, 15½ miles, at 7,000*l.* per mile	£108,500
Contingencies, 5 per cent.	5,425
	£113,925

Summary of outlay required in distributing the additional 30,000,000 gallons daily, increasing the supply to 230,000,000 gallons daily.

Service reservoir at Edgware, including land and contingencies, say		£100,000
Additional mains:—		
District No. 3	£153,300	
„ „ 4	113,925	
		267,225

	230,000,000		2,179,121

Total cost of works for obtaining 230,000,000 gallons daily from North Wales, and distributing same to existing centres of supply £10,317,205

THAMES SUPPLY.

No. 2. 1st Instalment.

Estimated outlay for works and annual working expenses, capitalized at 25 years' purchase, for obtaining an additional 35,000,000 gallons daily from the Thames, making a total supply of 130,000,000 gallons daily.

The additional supply will probably be required by the several companies in the proportions given in the following Table:—

Name of Company.	Present Supply, 1866.	Additional Supply.	Total Supply.
	Gallons.	Gallons.	Gallons.
New River	23,000,000	5,600,000	28,600,000
East London	19,300,000	7,300,000	26,600,000
Chelsea	8,000,000	1,150,000	9,150,000
Grand Junction	8,250,000	4,350,000	12,600,000
West Middlesex	8,700,000	4,600,000	13,300,000
Southwark and Vauxhall	12,700,000	6,700,000	19,400,000
Lambeth	9,000,000	2,250,000	11,250,000
Kent	6,050,000	3,050,000	9,100,000
	95,000,000	35,000,000	130,000,000

New River Company. Additional quantity required, 5,600,000 gallons daily.

Outlay in works.

APPENDIX O.

REPORT on the SELECTION of SAMPLES of WATER in the BASIN of the RIVER THAMES.—By WILLIAM POLE, F.R.S., Member of the Institution of Civil Engineers.

To His Grace the Chairman of the Commission.

MY LORD DUKE, Westminster, May 15, 1868.

1. I HAVE the honour to report that, in obedience to the instructions of the Commission, I have collected various samples of water within the drainage area of the river Thames, and have forwarded them for analysis by Drs. Frankland and Odling.

2. The localities where it was considered desirable that samples should be taken were settled generally by the Commission, and I have carefully carried out the instructions given me, using my own judgment in regard to the exact points of collection. These various points have all been marked on the Ordnance maps for reference.

3. The quantities taken were, as suggested by the chemists, four gallons for the more importtan samples, and two gallons for the rest. The manner of collection was the same as described in my former reports, Appendices A, B, and C.

4. The weather during the collection was generally fine, and, with one or two slight exceptions noticed in their proper places, the main river and the various streams appeared to be in their average condition, neither flooded nor low. It is probable, however, that the condition and quality of the water will vary considerably at different periods of the year, and under different conditions of weather, and will also depend on the quantity of water in the streams.

5. The general hydrography and geology of the basin of the Thames will be seen from the map published in the first Report of the Rivers Pollution Commission, 1866, and a great amount of information respecting it will be found in that publication, as well as in the evidence taken before the Royal Commission on Water Supply.

The portion of the basin above Ditton, the lowest point where water is taken for the supply of the Metropolis, extends over a length and breadth of 80 or 90 miles; its superficial area being given at 3,676 square miles.

The River Thames first assumes importance near the small town of Lechlade, where a number of small streams, forming the head waters of the river, unite. From this point down to Long Ditton, the river follows a tortuous course of about 120 miles in length.

It is joined on the north side by several important tributaries, the principal ones being the Windrush, the Evenlode, the Cherwell, the Thame, and the Colne; while on the south side it receives the waters of the Ock, the Kennet, the Loddon, the Wey, and the Mole.

6. Below Lechlade the Thames is canalized, the water being held up by locks, weirs, and sluices at intervals, forming successive pounds.

There appears to be no traffic worth speaking of in a large portion of this navigation; but the weirs have, I have no doubt, a very beneficial influence on the quality of the water, as its flow over them causes great agitation and aeration, and so must promote considerably the breaking up and oxidation of the organic matter. This fact I think ought to receive more consideration than hitherto in the discussion of the general economy of the river.

7. The samples taken may be divided into four classes, viz.:—

A. The head waters.
B. The main stream of the Thames.
C. The more important tributaries, north and south.
D. Certain outlying waters.

A.—HEAD-WATERS OF THE RIVER.

8. The portion of the Thames basin above Lechlade, containing what I have designated as the head-waters of the river, is above 400 square miles in extent, and is drained by several small streams, the principal of which are the Swillbrook, the Churn (passing through Cirencester), the Colne (Gloucestershire), the Leach, the Ray, and the Cole. Some of these streams were, when I saw them, running above 20 millions of gallons daily.

9. The surface of this large tract of country consists almost entirely of porous rock of the upper and lower oolite formations, interspersed with small areas of impervious fullers earth and lias clay. The oolites are covered generally with only a few inches of soil, and the rain is quickly absorbed. Hence the supply to the streams is principally from springs, the flow off the surface being small and partial except in very heavy rains. I was taken over a portion of the district by Mr. Bravender, of Cirencester, who is well acquainted with the geology and hydrography of the country, and who pointed out to me several of the most important springs.

10. Those in the northern portion of the district come from the lower oolite, being thrown up by the underlying lias clay. Of these I visited the well-known "Seven Springs" at the head of the Churn, which were delivering about 150,000 gallons per day; and a much more important one, the Syreford Spring, at the source of the Colne, furnishing about three or four millions of gallons.

11. The springs from the upper oolite, collected above the impervious bed called "fuller's earth," are more plentiful, and are dispersed over a wider area. They furnish, in fact, the great body of the water flowing down the streams. I saw many of these, and may mention the three following:—

1. The well at Thames Head, from which about 3,000,000 gallons of water are pumped daily, from a depth of about 35 feet below the surface, to supply the upper level of the Thames and Severn Canal.
2. The Boxwell spring, near South Cerney, which when I visited it was delivering about one or two million of gallons per day.
3. The springs in Ampney Park, about two miles east of Cirencester, which are very large, flowing on the 18th March between 5 and 10 millions of gallons.

12. The water from all these oolite springs was very clear and bright, the temperature being about 10° to 11° Cent. Probably the quality may not differ materially in the several places, but I have collected four samples as follows, and they may either be examined separately or mixed together, as the chemists may think best.

Syreford Spring (*Lower Oolite*).

Two gallons, bottle No. 61.

Thames Head Well (*Upper Oolite*).

Two gallons, bottle No. 38.

Ampney Park Springs (*Upper Oolite*).

Two gallons, bottle No. 28.

Boxwell Spring (*Upper Oolite*).

Two gallons, bottle No. 15.

B.—Main Stream of the Thames.

13. The various streams mentioned under the last head unite a little below Lechlade, forming a good wide river, which here becomes navigable, communicating with the south end of the Thames and Severn Canal.

14. The quantity of water passing down the river at this place I estimated roughly on the 18th April at something over 100 millions of gallons per day. In dry seasons it is no doubt much less, and in rains very much more. The water was slightly turbid, the bottom being visible, however, at two or three feet depth; and it had a temperature of 10½° Centigrade.

It is principally furnished by the oolite springs mentioned in the last head, with a little contribution from the chalk hills to the south, and probably some small proportion of surface drainage.

15. The towns of Cirencester, Cricklade, Lechlade, Fairford, Northleach, Swindon, Highworth, and some other small places, lie in the basin above this point, but as no systematic drainage by sewers (except to a small extent at Cirencester) is carried out in any of them, I think it may be said that the only contamination of importance received by the water is from the tilled land. And from the absorbent nature of the ground over nearly the whole of the district, this will naturally be much less than in places where the waters flow over retentive soils.

16. I have taken a sample from the river as it flowed through St. John's Bridge, about half a mile below Lechlade.

Thames at Lechlade.—Four gallons. bottles Nos. 2 and 14.

17. Descending the river from Lechlade, it receives on the north the water of the Windrush, Evenlode, and other small streams, and after a flow of about 27 miles it arrives at

Oxford,

which is the first large town on its banks, and where it receives a large tributary, the Cherwell.

18. With regard to this and the other large towns on the river, my instructions were to take three samples in each case, namely:

1. Immediately above the town, to show the natural quality of the water of the river uninfluenced by the population.
2. At a point below the town, where its drainage becomes mixed with the water.
3. At another point some miles below, but before the river receives any further affluent, or other important source of alteration, the object of this latter sample being to ascertain what change was produced on the quality by the flow.

In cases where, as at Oxford and Reading, a tributary entered at a town, it was necessary to take a sample of that tributary also.

19. Oxford, as I learnt from the borough surveyor, Mr. Field, and from Dr. Adams, of St. John's College (who has paid much attention to these questions), is drained to a considerable extent, though not so thoroughly as the modern system generally requires. There are two principal sewer outfalls, one emptying into the main stream just below Folly Bridge, the other into the Cherwell near the Botanic Gardens; and there are other smaller drains into both rivers.

20. The samples of the main river in the neighbourhood of Oxford were:—

At Midley Lock, about a mile above the town; taken on the 29th April, two gallons, bottle No. 25.

At "the Gut," about three-quarters of a mile below the junction of the Cherwell, same day, two gallons, bottle No. 95.

At the Lock above Abingdon, about seven miles below the place last mentioned; taken 30th April, two gallons, bottle No. 68.

The water at each of these places was tolerably clear, bottom visible at two or three feet deep; the samples near the town were the least so, probably owing to agitation by boating. Temperature about 13° or 14° Cent.

Reading.

21. The next part of the river at which samples were taken was in the neighbourhood of Reading, the object being, as in the case of Oxford, to ascertain the effect of the drainage of the town.

22. Reading, I am informed, has no systematic sewerage; there are some drains which open into the river Kennet as it passes through the town, and which carry off the surface water, but, as far as I can learn, they do not convey much house drainage, although, no doubt, a considerable amount of sewage somehow or other finds its way into the river. There is no drainage directly into the Thames, which is at some distance from the town.

23. Three samples were taken from the Thames in this neighbourhood, namely,

At Caversham Bridge, a little above the town; sample taken 24th April, two gallons, bottle No. 70.

Below the Town, about a quarter of a mile below the junction of the Kennet, and where consequently the river may be supposed to have received the drainage of the town; taken 24th April, two gallons, bottle No. 34.

At Shiplake Mill.—About four or five miles below point No. 2, and just above the entrance of the Loddon. Sample taken 25th April, two gallons, bottle No. 36.

In each of these places the river was tolerably clear, the bottom being visible at two or three feet deep. Temperature about 11° to 12° Cent.

24. Below this the river receives the Loddon, and after passing the town of Henley arrives at

Medmenham,

A point about four or five miles below Henley, where Messrs. McClean and Blackwell, in their plan of 1849, proposed to tap the river, and convey water by an aqueduct to London.

A sample, two gallons, bottle No. 35, was taken on the 25th April, close to Medmenham Abbey; water clear, bottom visible at about three feet depth.

Windsor.

25. The town of Windsor, and the Crown properties in the neighbourhood, are said to be efficiently sewered. The northern slope, drains by a small sewer into the south side of the river, a little west of the bridge leading to Eton, but the chief part of the sewage is conveyed into a sewer built by Government for the drainage of the royal properties, and which empties into the Thames about a mile below Datchett. The suburb of Eton drains, I believe, directly into the river.

26. I was told by a resident near the mouth of the main sewer, that the sewage does not flow regularly into the river, but is admitted by flashes, at intervals. This is not a good plan for the water in the river, as it is unfavourable to the gradual oxidation of the organic matter.

27. I took on 2nd May three samples from the river near this place.

Above Windsor.—About half a mile above the bridge, clear of the town and the sewage; sample two gallons, No. 43; water very clear and clean; bottom visible many feet deep.

Below sewer outlet.—I could not find a convenient place to take this till I came to the ferry at Old Windsor. This is nearly two miles below the mouth of the sewer, and the water, though it continued clear, presented traces of dirt, straw, &c. floating on and in it. Sample two gallons, bottle No. 51.

At Weir above Staines.—The third sample was taken under the Weir above Staines, and just above the entrance of the Hertfordshire Colne. This point is nearly three miles below the last-named one, and five miles below the outlet of the Windsor sewage. Sample two gallons, bottle No. 96; water clear and cleaner looking than at the place of the second sample.

Hampton.

28. The lowest sample of the river was taken on the 4th May, just above the place where the Southwark and Vauxhall, Grand Junction, and West Middlesex Companies take their water; that is, about a mile above the village of Hampton. Sample four gallons, bottles Nos. 67 and 92; water clear, bottom visible 4 or 5 feet deep. Temperature 17° Cent.

C.—Tributaries.

29. It was not considered necessary to take samples of all the tributaries to the Thames. Those selected were the principal ones, namely, the Cherwell, the Thame, and the Colne on the north, and the Kennet, the Loddon, the Wey, and the Mole on the south of the main stream.

The Cherwell.

30. The Cherwell is a large stream, which enters the Thames at Oxford, and drains about 400 square miles of country, consisting chiefly of oolite, Oxford clay, and lias. The quantity of water brought down was large, but I had no means of estimating its amount.

I took on the 29th April a sample at Cox's ferry, a mile or two above Oxford, four gallons, bottles Nos. 60 and 80. Water tolerably clear, like the Thames; temperature 12½° Cent.

The Thame.

31. This is a stream flowing in at Dorchester; it drains between 300 and 400 square miles, to some extent chalk, but principally Kimmeridge clay.

The sample was taken 30th April, at Queenford mill, just above Dorchester; four gallons, bottles Nos. 17 and 29. Water rather turbid, bottom visible at 12 to 18 inches deep; temperature 14° Cent.

The Colne (Hertfordshire).

32. The river Colne forms the outlet for a great body of water issuing by springs from the large area of chalk lying to the north-west of London. Its drainage ground appears by the map to be upwards of 400 square miles in extent, and from its proximity to London, and from the natural purity of its water, it has often been proposed as a source of supply.

The river itself having many mills upon it, it was thought preferable that I should take the sample direct from one of the chalk springs forming its principal feeders, and I chose for the purpose one well known, lying two or three miles above Watford, called the Otter's Pool.

The sample was taken on the 8th April, four gallons, bottles Nos. 56 and 89. The spring was delivering about two and a half millions of gallons per day, and the water was perfectly clear; temperature about 11° Cent.

The Kennet.

33. This river, which is one of the chief feeders of the Thames, drains between 400 and 500 square miles of country, and falls into the main stream a little below Reading.

It comes chiefly from the chalk downs north of Hungerford and Marlborough, and in the lower part of its course flows over clay beds in the valley.

On the 24th April after a few days of showery weather I found it near its junction with the Thames running at a rough estimate about 200 millions of gallons per day.

I took two samples of this river as follows:—

Above Hungerford.—This was taken on the 20th April, about a mile above Hungerford; quantity, 4 gallons; bottles Nos. 24 and 74. Water clear; temperature about 11° Cent.

Above Reading.—This was taken on the 24th April, rear the site of the waterworks pumping station, about two miles above Reading. Quantity 2 gallons; bottle No. 65. The water here was rather turbid, the bottom being, however, visible about 18 inches deep.

The Loddon (Bagshot Sands).

34. The tributary stream called the Loddon, which falls into the south side of the Thames about 5 miles below Reading, drains partly a tract of London clay, and partly, by means of the Blackwater, a district of porous strata known as the "Bagshot Sands," about 200 square miles in extent, and which was some years ago proposed as a source of supply for the metropolis on account of the supposed superiority of its waters.

Instead of taking samples from the Loddon, it was deemed more useful to get them direct from the Bagshot Sand district, and for this purpose I was kindly directed by Professor Rupert Jones, of Sandhurst College, to a small stream which is used for the supply of that establishment and which was stated by him to present a fair sample of the water as naturally flowing from the formation in question. It rises at Wishmoor and runs into the Blackwater near Blackwater station on the Reading and Guildford railway.

The sample, 4 gallons, bottles Nos. 23 and 53, was taken on the 21st April, about a mile above the college; temperature about 11° Cent. The water was clear, but a little coloured by peat, and the channel presented appearances probably due to iron.

The Wey.

35. The Wey drains between 400 and 500 square miles of country, passing through Guildford, and joining the Thames near Weybridge.

Above Guildford it comes principally from the Lower Green-sand formation, with, however, a mixture of chalk water from the neighbourhood of Farnham and Alton. Below Guildford it collects the eastern drainage of the Bagshot Sands.

A sample of the water, 4 gallons, bottles Nos. 37 and 49, was taken on the 21st April about three-quarters of a mile above Godalming; river somewhat in flood and rather turbid; temperature about 13° Cent.

Mole.

36. The River Mole drains about 200 square miles of country; running by Dorking, Leatherhead, and Cobham, and joining the Thames opposite Hampton Court. The upper part of the district above Dorking is chiefly Weald clay, the lower part below Leatherhead, chiefly London clay.

The sample, 4 gallons, bottles Nos. 59 and 84, was taken on the 4th May, about one mile above the junction and above the village of Moulsey. Water dirty and turbid, bottom hardly visible 1 ft. deep.

D.—Outlying Waters.

37. In addition to the waters properly belonging to the drainage area above Ditton, I was instructed to take samples from other parts of the basin which would afford useful information on the subject of the supply of the metropolis. These are as follow:—

River Lea district.

38. The upper waters of the Lea being used for the supply of London by the New River and East London companies, it was considered desirable to have samples, and I accordingly took them, on the 5th May, from three places, as follows:—

Lea proper.—Taken from a point just above Woolmers Park, about three or four miles above Hertford; two gallons, bottle No. 86. Water clear, but with particles of dirt, straw, &c. floating in it. Temperature, about 16° Cent. Quantity, about ten millions of gallons per day.

Mimram.—Taken from the bridge in Panshanger Park, about two or three miles above Hertford; two gallons, bottle No. 3. Water like the last. Temperature, about 14½° Cent. Quantity about the same as the Lea.

Amwell Spring.—This sample, four gallons, bottles Nos. 22 and 76, was taken as pumped from the New River Company's well at Amwell Hill, about a mile below Ware. Water beautifully clear. Temperature, 11° Cent.

Chalk district, south of London.

39. This is a district which it is believed collects a large quantity of water, that at present finds its way into the Thames by the Wandle, the Ravensbourne, and the Darenth, and is to a small extent used by the Kent Water Company for the supply of the south-eastern districts of London.

To obtain a specimen of this water I visited on the 12th of May the waterworks established by Mr. Homersham on the high ground south of Caterham, for the purpose of supplying that place, as well as the neighbouring districts of Godstone, Bletchingly, Nutfield, and Red Hill. The water is pumped from a very deep well, the water standing about 300 or 400 feet below the level of the ground at the pumping station, which is 700 feet above the sea. The water is softened by Dr. Clark's process (as described in Mr. Homersham's evidence), and stored in an underground reservoir for distribution.

The sample, four gallons, bottles Nos. 97 and 100, was taken from the pumping main, as it came directly from the well, and probably represents fairly the chalk water of the North Downs. The temperature was 11° Cent.

Croydon and the Wandle.

40. The object of these samples was to obtain some knowledge as to the operation of the plan now adopted for applying the sewage of Croydon to irrigate land, before it is turned into the River Wandle.

41. The works have been designed and laid out by Mr. Baldwin Latham, the borough engineer, who gave me every assistance in my examination. The town,

containing between 30,000 and 40,000 inhabitants, is amply supplied with water from a well in the chalk, near the centre of the town. The sewerage is systematically laid out, and the sewers draining the greater portion of the area open at the western outskirts of the town, towards the River Wandle. The sewage running from them, which I am told averages about 3,000,000 gallons per day, is first roughly strained, to arrest the larger solid matters, and then is conducted to the irrigation land at Beddington, which has been acquired for the purpose by the town. The whole area of this land is, I am told, about 300 acres, and the drains are so laid out as to carry the sewage to all parts; but only about 20 or 30 acres are under irrigation at one time. The land is on a gentle slope, and the liquid, being turned upon it at the upper end flows over the whole surface, and passes off into drains at the bottom, from which it is conveyed away into the River Wandle, about half way between Carshalton and Mitcham.

42. When I saw the system at work on the 11th May, although the sewage was foul and dirty when it went on to the land, the water running off was quite bright and clear, without any appearance of foul deposit in the channel. I noticed several fine trout in the river, near the point of discharge, as well as in other places farther down.

It is worthy of remark that the plan here adopted, of allowing the sewage to travel slowly over the land, in constant agitation among the blades and stalks of the vegetation, appears to me peculiarly favourable for the oxidation of the impurities by the action of the atmosphere, which I have no doubt powerfully aids the purifying action by vegetable absorption. I noticed, however, that the person working the plan had the power of allowing the sewage, or any portion of it, to run by bye passes directly into the effluent channel, and so into the river, without passing over the fields; a dangerous power, as either through carelessness or design the whole efficacy of the system might thereby be destroyed.

43. I took in this neighbourhood five samples of two gallons each, viz.:—

(1.) *From the well supplying Croydon with water.*
Bottle No. 83, temperature 13½° Cent.

(2.) *Sample of the sewage as it passes on to the land,* after simple straining.
Bottle No. 21, temperature 12° Cent.

(3.) *Sample of the purified sewage water* as it passes into the Wandle after running off the land.
Bottle No. 8, temperature 16° Cent.

(4.) *Sample from the Wandle,* about half a mile below the place where it receives the sewage water.
Bottle No. 90, temperature 14° Cent.

(5.) *Sample from the Wandle,* on Mr. Bidder's property at Mitcham, about a mile below the last-named point.
Bottle No. 94.

44. With regard to the quality of the water in the Wandle, it must be remarked that there are many mills on the stream, above the two points where my samples were taken, and several of these, I am given to understand, turn noxious matters into the river.

List of the Samples.

45. The following is a list of the samples, arranged in order.

Head Waters.

Gallons.
2. Syreford spring.
2. Thames head well.
2. Ampney Park springs.
2. Boxwell spring.

Main Stream.

Miles from Lechlade.	Gallons.	
½	4	At St. John's Bridge.
25½	2	At Midley Lock, above Oxford.
28½	2	At the Gut, below Oxford.
35	2	At the Weir, above Abingdon.
65	2	At Caversham Bridge, above Reading.
66½	2	A little below Reading.
70½	2	At Shiplake.
79	2	At Medmenham.
96½	2	Above Windsor.
104	2	At weir above Staines.
101	2	Below Windsor sewers outfall.
116½	4	At Water Companies' intake at Hampton.

Tributaries.

Gallons.
4 Cherwell.
4 Thame.
4 Chalk spring (Colne).
4 Kennet, above Hungerford.
2 Do., above Reading.
4 Bagshot Sands (Loddon).
4 Wey.
4 Mole.

Outlying Waters.

Gallons.
2 Lea proper } Above Hertford.
2 Mimram }
4 Amwell well.
4 Caterham well.
2 Croydon well.
2 Do. sewage.
2 Do. do. purified.
2 Wandle, after mixture.
2 Do. at Mitcham.

I have, &c.
William Pole.

APPENDIX P.

Returns of the Quantities of Water supplied by the Metropolitan Water Companies in former Years.

CHELSEA WATERWORKS COMPANY.

Return of Average Daily Quantity of Water, and Number of Houses supplied from 1857 to 1867, both inclusive.

Date.	Average daily quantity, gallons.	Number of houses supplied.
1857	5,503,700	25,271
1858	5,780,000	25,584
1859	5,788,700	25,711
1860	5,909,600	25,850
1861	6,233,500	25,936
1862	6,811,600	26,049
1863	7,187,900	26,234
1864	7,977,800	26,362
1865	8,394,700	26,436
1866	7,918,400	26,783
1867	8,087,300	27,077

15th May 1868.

WEST MIDDLESEX WATERWORKS COMPANY.

19, Marylebone Road, W.
16th May 1868.

Sir,

Your letter of the 27th ult. having been referred by the Board of Directors to the Company's Engineer for his report, I am desired to forward you the following statement of the average daily quantity of Water, and of the number of Houses supplied by this Company for the years from 1856 to 1867, both inclusive, viz.:—

Date.	Average Daily Supply in Galls.	Number of Houses.
1856	6,005,293	28,198
1857	6,007,608	28,773
1858	6,191,424	29,300
1859	6,313,248	30,101
1860	6,288,408	30,793
1861	6,716,302	31,441
1862	6,924,744	32,217
1863	7,090,848	33,137
1864	7,499,088	34,198
1865	8,046,000	35,303
1866	8,208,168	36,331
1867	8,790,336	37,570

The Directors have no reliable data upon which they can depend to enable them to furnish you with a return of the number of persons resident in the houses supplied by the Company.

I am, &c.,
W. H. Whiffin, Secretary.

To Dr. Wm. Pole, F.R.S., Secretary, &c.
Royal Commission of Water Supply.

SOUTHWARK AND VAUXHALL WATER-WORKS COMPANY.

RETURN of the AVERAGE DAILY QUANTITY of WATER supplied by the above COMPANY for 12 years, commencing Christmas 1856 and ending Christmas 1867.

Date.	Average Daily Supply in Imperial Gallons.	No. of Houses supplied.
For the year ending—		
Christmas 1856 -	Supplied for 6 days in the week, and a small portion on Sundays. 10,331,122	41,432
,, 1857 -	10,604,537	43,721
,, 1858 -	10,621,349	45,909
,, 1859 -	10,873,415	46,737
,, 1860 -	10,732,458	48,911
,, 1861 -	11,155,000	52,220
,, 1862 -	11,244,177	56,444
,, 1863 -	11,322,431	60,413
,, 1864 -	11,500,231	64,725
,, 1865 -	Supply given 7 days per week. 12,120,778	69,111
,, 1866 -	12,502,000	73,940
,, 1867 -	13,050,563	71,229*

The number of inhabitants in this company's district is roughly estimated at 6½ persons per house.

GRAND JUNCTION WATERWORKS COMPANY.

RETURN of the AVERAGE DAILY QUANTITY of WATER supplied by the above Company for 12 years, commencing Michaelmas 1855, and ending Michaelmas 1867.

Date.	Average Daily Supply in Imperial Gallons.	No. of Houses supplied.
For the year ending—		
Michaelmas 1856 -	5,478,361	17,080
,, 1857 -	6,022,651	17,722
,, 1858 -	6,858,465	18,357
,, 1859 -	8,416,596	18,996
,, 1860 -	7,118,486	19,663
,, 1861 -	7,733,250	20,336
,, 1862 -	8,455,179	21,184
,, 1863 -	8,330,293	22,769
,, 1864 -	8,701,275	23,036
,, 1865 -	9,780,057	24,333
,, 1866 -	9,317,055	26,450
,, 1867 -	9,392,768	27,032

N.B.—The number of inhabitants is roughly estimated in this company's district at nine persons per house.

ERNEST O. LEE,
9th May 1868. Secretary.

LAMBETH WATERWORKS COMPANY.

RETURN of AVERAGE DAILY QUANTITY of WATER and NUMBER of HOUSES supplied from 1857 to 1867, both inclusive.

Date.	Average Daily Quantity. Gallons.	No. of Houses supplied.
1857 - - -	6,052,300	29,295
1858 - - -	5,935,900	30,143
1859 - - -	5,708,200	30,745
1860 - - -	6,026,700	31,571
1861 - - -	6,557,600	32,271
1862 - - -	6,962,700	33,340
1863 - - -	7,765,600	34,353
1864 - - -	8,650,200	35,005
1865 - - -	9,030,400	35,420
1866 - - -	8,950,600	37,165
1867 - - -	8,975,500	39,460

W. S. PHIPPS,
Office of Lambeth Waterworks, Secretary.
175, Kennington Park Road,
14th May 1868.

* The smaller number is in consequence of the number of houses pulled down for railways and improvements.

NEW RIVER COMPANY.

Date.	Average Daily Supply in Gallons.	Average Number of Houses served.
1858 - - -	24,992,334	101,534
1859 - - -	24,988,151	103,514
1860 - - -	20,801,277	105,007
1861 - - -	22,837,000	106,303
1862 - - -	23,260,341	107,977
1863 - - -	23,834,673	109,482
1864 - - -	24,718,452	110,511
1865 - - -	23,496,866	111,447
1866 - - -	22,898,769	112,252
1867 - - -	23,818,231	113,464

12th May 1868. ALEX. INGLIS, Secretary.

EAST LONDON WATERWORKS COMPANY.

Office 16, St. Helen's Place, E.C.,
20th May 1868.

Date.	Gallons pumped daily.	Number of Houses supplied.
	365 days all.	
1830 - - -	4,987,272	43,894
1840 - - -	6,695,624	48,991
1850 - - -	9,908,355	58,129
1851 - - -	10,629,176	59,550
1852 - - -	11,543,521	61,451

1861 - - -	16,837,278	78,494
1862 - - -	16,941,315	80,387
1863 - - -	17,571,937	83,296
1864 - - -	17,381,104	85,557
1865 - - -	18,333,067	88,340
1866 - - -	19,380,740	91,975
1867 - - -	19,320,576	95,098

E. BATES, Secretary.

KENT WATERWORKS COMPANY.

RETURN of the NUMBER of HOUSES supplied, and the AVERAGE DAILY CONSUMPTION of WATER, from 1839 to 1867.

Date.	Average Daily Supply in Gallons.	Houses supplied.
1839 - - -	360,000	5,600
1840 - - -	380,000	5,832
1841 - - -	399,000	5,985
1842 - - -	409,000	6,308
1843 - - -	437,000	6,547
1844 - - -	470,000	6,939
1845 - - -	600,000	7,681
1846 - - -	923,000	8,381
1847 - - -	1,010,000	9,223
1848 - - -	1,070,000	9,662
1849 - - -	1,258,000	10,456
1850 - - -	1,575,000	11,486
1851 - - -	1,769,000	12,536
1852 - - -	2,000,000	13,588
1853 - - -	2,146,000	14,573
1854 - - -	2,686,000	15,650
1855 - - -	2,757,000	15,716
1856 - - -	2,722,000	16,662
1857 - - -	2,936,000	17,774
1858 - - -	3,415,000	18,875
1859 - - -	3,594,000	20,125
1860 - - -	3,987,000	21,533
1861 - - -	4,546,000	26,362
1862 - - -	4,869,000	28,125
1863 - - -	4,894,000	29,560
1864 - - -	5,284,000	30,802
1865 - - -	5,463,000	32,451
1866 - - -	6,038,000	33,864
1867 - - -	6,520,000	35,607

W. R. MORRIS, Engineer.

PROPOSED

SCHEME FOR THE

SUPPLY OF WATER

TO VARIOUS TOWNS FROM THE LAKE DISTRICTS OF

CUMBERLAND & WESTMORELAND,

By

THOS DALE C.E.

CORPORATION WATERWORKS, HULL.

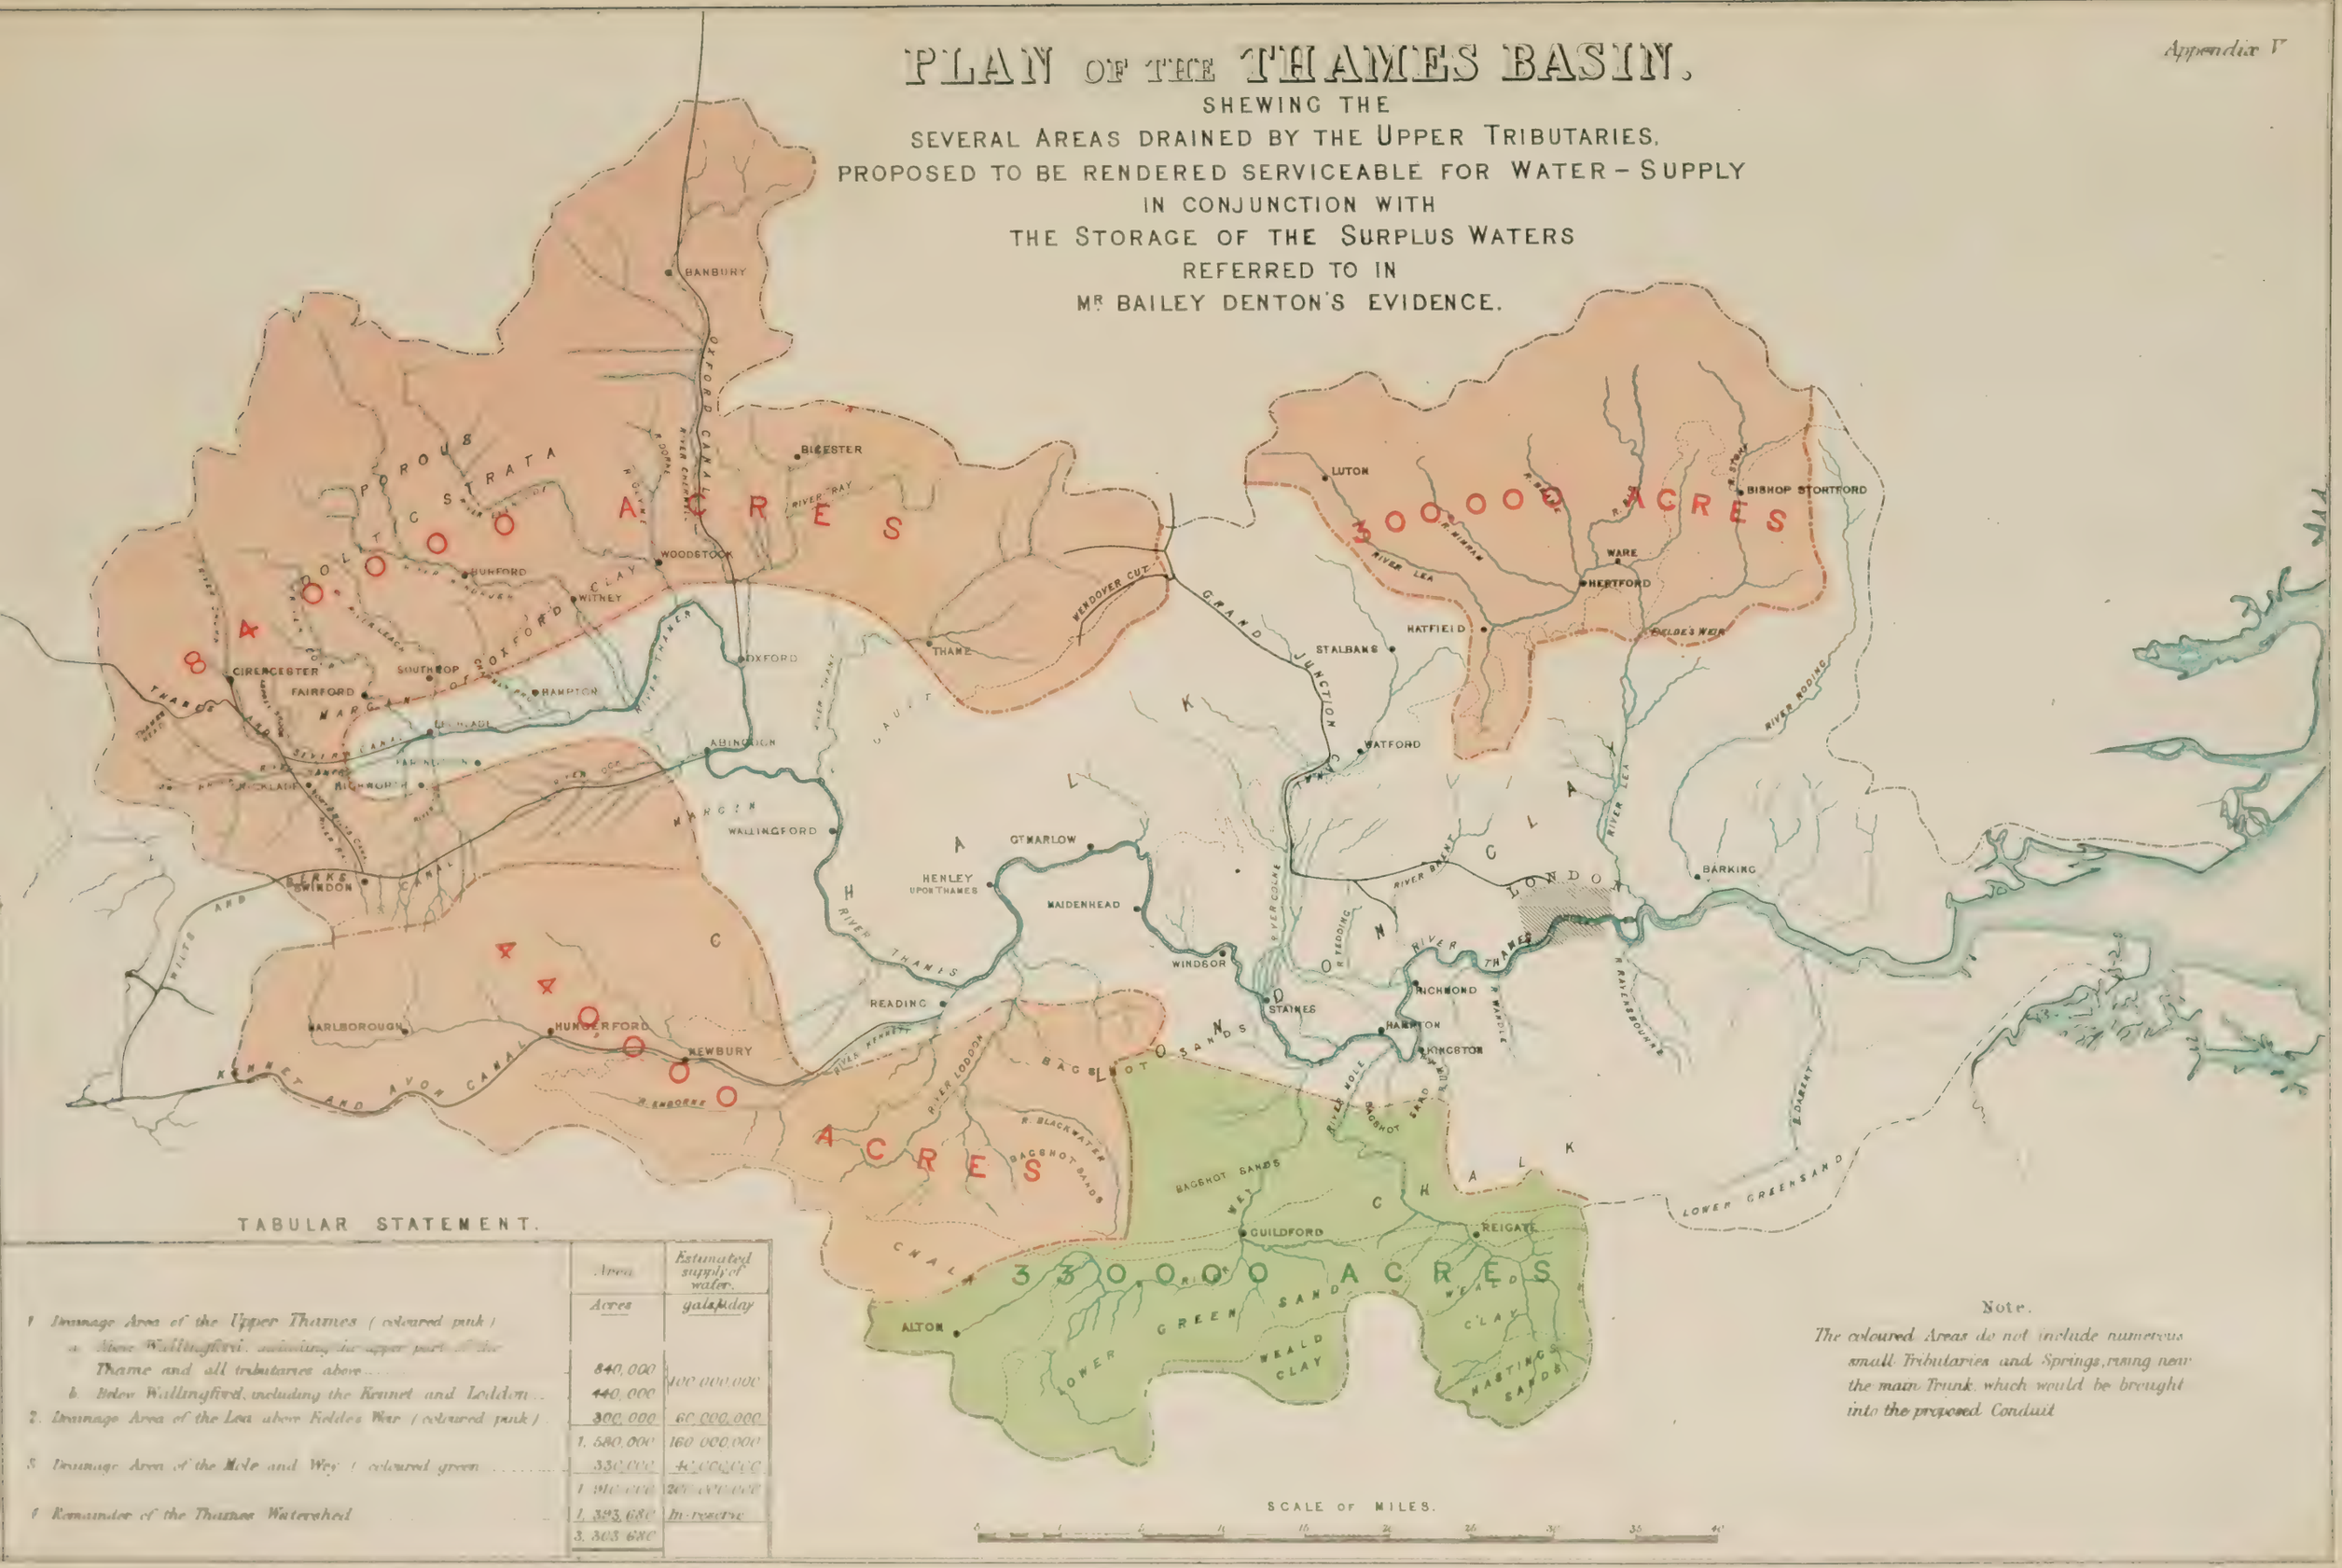
PLAN OF THE THAMES BASIN.

SHEWING THE
SEVERAL AREAS DRAINED BY THE UPPER TRIBUTARIES,
PROPOSED TO BE RENDERED SERVICEABLE FOR WATER-SUPPLY
IN CONJUNCTION WITH
THE STORAGE OF THE SURPLUS WATERS
REFERRED TO IN
MR BAILEY DENTON'S EVIDENCE.



TABULAR STATEMENT.

	Area	Estimated supply of water.
	Acres	gals/day
1. Drainage Area of the Upper Thames (coloured pink)		
a. Above Wallingford, including the upper part of the Thame and all tributaries above	840,000	100,000,000
b. Below Wallingford, including the Kennet and Loddon	440,000	
2. Drainage Area of the Lea above Edles Weir (coloured pink)	300,000	60,000,000
	1,580,000	160,000,000
3. Drainage Area of the Mole and Wey (coloured green)	330,000	40,000,000
	1,910,000	200,000,000
4. Remainder of the Thames Watershed	1,393,680	In reserve
	3,303,680	

Note.

The coloured Areas do not include numerous small Tributaries and Springs, rising near the main Trunk, which would be brought into the proposed Conduit

APPENDIX AF.

Extract from Report of the Commissioners on the Chemical Quality of the Supply of Water to the Metropolis.—(Parl. Paper, 426, Sess. 1851.)

Specimens of the water of all the companies were taken for analysis, always from a main and generally at the nearest accessible point to the works of the company, or to a distributing reservoir. They were all drawn on the 29th, 30th, and 31st of January last, after moderately rainy weather, with the river full but not flooded. The specimens may be considered as representing the least favourable state of the water supply to the metropolis during winter, but still such as it may continue for several months in a wet season like the last. The temperature of the river at the time was 44° Fahrenheit.

The results are given in two forms, first the acids and bases separately, as actually found by analysis, and secondly the same acids and bases arranged in the form of salts, or chemically combined as they are believed to exist in the waters.

The first group consists of waters not derived from the Thames.

The waters were all sensibly tinged of a yellow or ochry tint, due chiefly to suspended clay, with the exception of the Kent water, which was clear and bright. This turbid condition of the waters was represented to us as having subsisted for two months, but was rather on the decline at the time of observation. It was least marked in the Chelsea, Grand Junction, and West Middlesex Waters, which are filtered by the companies. These waters did not allow the suspended matter to fall entirely on standing in a glass jar, but remained sensibly coloured after several weeks of rest; they might all, however, we believe, be perfectly clarified by the use of a properly constructed house-filter. The Thames Ditton water was taken from a main in Surbiton, near the company's works, at a later period of the season than the others, namely, on the 22d of February, and was clear and bright. It is a filtered water.

The soluble organic matter from two of the Thames waters was submitted to ultimate analysis, and found to give 0·105 grain of nitrogen in the Grand Junction water, and 0·031 grain of nitrogen in the Southwark and Vauxhall water. The existence of nitrogen is generally supposed to imply the animal origin of organic matter, and on such evidence a minute and probably unimportant portion of animal organic matter would be admitted to be present.

None of the waters had marked taste or odour, nor betrayed any indication of putrescence, either when first taken up or after being kept in bottles for several weeks at a temperature between 50° and 60°; nor even after remaining in close vessels for two weeks at 80°.

In these waters when submitted to microscopic examination no animalcules were observed in any case. But the period of the year was not that at which any considerable development of animal life is to be looked for.

All the waters under consideration have much of a common character, arising from the similar geological conditions of their sources. Every one of them is derived in a great proportion from the chalk formation, of which the waters have peculiar properties. This appears, both in the degree and the nature of the hardness they exhibit, which is due to the presence of salts of lime and magnesia in solution.

All the samples of Filtered Water drawn from the Mains were clear, and when examined in a glass tube two feet in length, they had only a very pale greenish yellow tinge. Judging from this, and from the small amount of oxygen required to oxydise the organic matter, it could not in any case have exceeded a grain per gallon of water, or one part in seventy thousand parts.

The proportion of ammonia was also very small—the range being from the 1-1,000th of a grain per gallon of water, to the 4-1,000th of a grain per gallon—that is, from one part of ammonia in seventy million parts of water to one part in seventeen and a half millions.

These results are the averages of the corresponding months in the two years (1865 and 1866), and they show that, in the case of the Thames and River Lea, the *maximum* amount of solid matter is found in the water during the winter months, when the rainfall is greatest and the evaporation least; and the *minimum* amount of solid matter is found in the water in the months of July, August, and September, when the rainfall is least and the evaporation greatest.

The Returns of 1851 are taken from the Report by the Government Commission on the Chemical Quality of the supply of Water to the Metropolis in 1851; and those of 1856 are taken from the Reports to the Right Hon. William Cowper, M.P., President of the General Board of Health on the Metropolis Water Supply in 1856.

* This total includes 427,468 gallons of water daily, supplied by the Hampstead Company in 1851.

† This total includes 603,060 gallons of water daily, supplied in 1856 by the Hampstead Water Company, and 550,000 gallons supplied in the same year by the Plumstead, Woolwich, and Charlton Water Company.

In 1851 the population of London was 2,362,236; consequently there were 19·4 gallons of water supplied per head of the whole population.
In 1856 " " 2,583,112; " " 30·2 " "
In 1867 " " is 3,067,536; " " are 30·9 " "

APPENDIX AH.

REPORT on the QUALITY of the WATERS supplied by the METROPOLITAN WATER COMPANIES in May, June, and July, 1868, with Tables and Analyses.

To James Simpson, Esq.

SIR,

IN accordance with your instructions of the 18th of May last, on behalf of the several Metropolitan Water Companies, to the effect that we would collect and analyze samples of the water supplied by them in 1868, and report to you thereon, we have now to submit a Tabular Statement of the analytical results arrived at by us (vide appended Tables Nos. 1 and 2) in the examination of samples collected at the following under-mentioned places:

At the Cab-rank, Portland Road, from main of West Middlesex Company.

At the Cab-rank, Piccadilly, from main of Grand Junction Company.

At the Cab-rank, St. George's Church, from main of Southwark and Vauxhall Company.

At the Cab-rank, Lambeth Baths, from main of Lambeth Company.

At the Cab-rank, Whitehall, from main of Chelsea Company.

At Public Tap, Aldgate, from main of New River Company.

At London Hospital, from main of East London Company.

At New Cross, from main of Kent Company.

1. On reference to table No. 1, it will be observed that the hardness of the water supplied by the Thames Companies ranges from 11·3° to 12·5°—that from the New River being 11·0°; while the water from the East London Company has a hardness of 11·7°; and that of the Kent Company a hardness of 17·6°.

After boiling for fifteen minutes, the hardness of the water from the Thames Companies is reduced to between 2·4° and 3·5°; the New River water to 2·3°; the East London water to 2·6°; and the Kent Company's water to 6°.

On comparing these results with the return of analyses made by us in the winter of 1866–7 (in reference to the Metropolis Water Inquiry, conducted by a Committee of the House of Commons in 1867) it will be observed that, in all instances, excepting that of the Kent Company's water (derived solely from deep wells) the hardness is less than that of the water collected during the winter season, a result which is in accordance with previous experience regarding the fluctuations in the composition of river water at different seasons.

2. The total proportion of dissolved gases is, as might have been anticipated, a little lower than in the colder season; but it is observable that the amount of carbonic acid in the water is somewhat higher than it was in the winter, the nitrogen and oxygen being consequently present in lower proportions. Taking the average of the Thames companies' supplies, it may be said that the proportion of oxygen dissolved in the Thames water amounts to 0·661 grains per gallon; that in the New River water amounts to 0·666 grains, while the East London water supply contains 0·645 grains, and the Kent Company's water 0·532 grains. The proportion of oxygen is, in the case of the Thames water, about eight times the amount required for the oxydation of the existing oxydizable matters (as indicated by the permanganate test); in the case of the New River water it amounts to about fourteen times; in that of the East London Company to about eleven times; and in that of the Kent Company to rather more than twenty times that required for the above purpose.

3. With respect to the ammonia existing in the water supplies, the proportion ranges from 0·001 to 0·002 grains per gallon, and is, in most instances, about the same as was found in the water during the winter of 1866-7.

4. The second table gives the proportions of the several saline constituents and of the volatile matter contained in an Imperial gallon of each of the companies' waters.

The observation which has been already made respecting the difference in the hardness of the several samples examined, in the winter and in the summer, applies also, generally, to the saline constituents, which are somewhat lower in amount at the present time than when we last examined the waters.

With reference to the second part of your letter, in which you request us to report on the system pursued by Dr. Frankland in obtaining and recording his analytical results, we have to offer the following few remarks.

Without discussing the question of the general applicability of Dr. Frankland's method of water analysis, which are at present we believe almost exclusively employed by him, we must express our dissent from one of the inferences which he founds upon his analytical results. In particular, we contend that the proportion of nitrogen discovered in water, in the forms of nitric acid, ammonia, &c., is not a trustworthy measure of the extent to which that water has, at some time or other, been contaminated by sewage, inasmuch as the nitrogen compounds existing in a water may, on the one hand, greatly exceed, and, on the other, equally fall short of those which would be furnished by the addition to the water of a given proportion of sewage (using the latter term in the broad sense in which it has been applied by Dr. Frankland); thus, for example, we cannot accept as a

correct representation of the relative condition of the East London water (from the river Lea), and that supplied by the Kent Company from deep wells in the chalk, the statement of Dr. Frankland in the Registrar General's Weekly Return for May last (No. 22, page 179) that the former contains 0 parts of previous sewage contamination (estimated) in 100,000 parts of water, while the latter exhibits 3,540 parts of previous sewage contamination in the same amount of water.

It scarcely need be pointed out by us, that the apparently higher results which Dr. Frankland's published analyses record, as to the solid constituents generally existing in water, when compared with those given in the reports of other analyses, are simply ascribable to the circumstance that they are calculated on 100,000 parts of water instead of on the Imperial gallon of 70,000 parts, as is the general custom.

In conclusion, we have to express our opinion that no useful results, but the reverse, can be attained by expressing in large multiples, as in tons (see Registrar General's weekly returns) the small proportions of mineral or other constituents, which analysis discovers in potable waters, and by designating as *impurities*, perfectly harmless substances which exist, in varying proportions, as normal constituents of nearly all natural waters.

We remain, &c.,

Hy. Letheby, M.B., M.A., &c.,
Professor of Chemistry in the London Hospital, and Medical Officer of Health for the City of London.

F. A. Abel, F.R.S., &c.
Chemist to the War and Ordnance Department, Woolwich.

W. Odling, M.B., F.R.S., &c.,
Professor of Chemistry in St. Bartholomew's Hospital.

London Hospital, July 13, 1868.

APPENDIX AJ.

Examples of the Registrar General's Monthly Reports on the London Waters.

Report for February 1867.

Royal College of Chemistry,
March 8th, 1867.

Sir,

I have the honour to submit to you in the following table the results of the chemical examination of the waters supplied to the metropolis during the month of February last.

Analysis of the Metropolitan Waters in February 1867. By Professor Frankland, F.R.S., of the Royal College of Chemistry.

Companies.	Date and Place of Collection.	Total Solid Impurity.	Organic Carbon.	Nitrogen, as Nitrates and Nitrites.	Ammonia.	Total Combined Nitrogen.	Previous Sewage Contamination (estimated).	Total Hardness.
Thames.

Column 1	2	3	4	5	6	7	8	9

* This company does not supply London.

The numbers in columns 3, 4, 5, 6, 7, 8, and 9 all relate to 100,000 parts of the waters. Column No. 3 shows the tota lsolid impurity contained in each water as delivered from the companies' mains. No. 4 shows the amount of carbon contained in the organic matter present in this solid impurity. No. 5, the amount of nitrogen in the form of salts of nitric and nitrous acids. Column No. 6 gives the amount of ammonia present in each sample, whilst column No. 7 records the total amount of nitrogen in the several forms of nitrogenous organic matter, salts of nitric and nitrous acids and ammonia. The most objectionable impurities contained in water supplied for domestic purposes are organic matters of animal origin, such as those contained in sewage and in the manure of cultivated land. After admixture with river or spring water these organic matters undergo slow oxidation, by which they are more or less completely resolved into comparatively innocuous inorganic compounds; their carbon is converted into carbonic acid and their hydrogen into water, and these products can no longer be identified in the aërated waters of the river or spring, but the nitrogen, which is an essential constituent of these noxious organic matters, is converted into nitrous and nitric acids, which, combining with the bases contained in most waters, remain dissolved, and constitute a record of the sewage or other analogous contamination to which the water has been subject. With certain corrections, the analytical determination of the nitrogen contained in these salts and in the form of ammonia writes, as it were, the history of the water as regards its contact with decomposing animal matter. Such *previous organic contamination* may be conveniently expressed in parts of average filtered London sewage, which if contained in 100,000 parts of the water, would produce the same results when thus completely oxidized. This previous sewage contamination or its equivalent is given in column 8, average filtered London sewage being taken as containing 10 parts of combined nitrogen in 100,000 parts, as deduced from the numerous analyses of Way, Hofmann, and Witt. Finally, column 9 expresses the amount of carbonate of lime, or its equivalent of other hardening salts, contained in 100,000 parts of the waters.

The table will now be intelligible; it may be thus read: 100,000 lbs. of East London water collected on 16th February at a cab rank in Shoreditch contained 33·56 lbs. of solid impurity; the organic matter, constituting a portion of this impurity, contained 0·293 lb. of carbon. This solid impurity also contained 0·357 lb. of nitrogen in the shape of nitrates and nitrites, besides 0·004 lb. of ammonia, whilst the total amount of *combined* nitrogen in every form was found to be 0·392 lb. Such combined nitrogen is to be carefully distinguished from the *uncombined* nitrogen of the air which is present in all natural waters. The above quantity of water supplied by the East London Company had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 2,620 lbs. of average filtered London sewage. By gradual oxidation, partly in the pores of the soil, partly in the river Lea, and partly in the reservoirs, filters, and conduits of the East London Company, this sewage contamination had been entirely converted into comparatively innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 parts of the East London water contained 18·8 lbs. of carbonate of lime, or their equivalent of other soap-destroying ingredients.

I have, &c.
E. Frankland.

The Registrar General,
&c. &c. &c.

Report for March 1867.

Royal College of Chemistry,
March 30th, 1867.

Sir,

I have the honour to submit to you in the following table the results of the chemical examination of the waters supplied to the metropolis during the present month. For the purpose of comparison I append also the results yielded by Loch Katrine water, as supplied to Glasgow, when submitted to the same analytical processes.

Analysis of the Metropolitan Waters in March 1867. By Professor Frankland, F.R.S., of the Royal College of Chemistry.

East London	15th March, Old Ford Waterworks	30·36	·270	·320	·004	·323	2245	18·3
Kent	15th March, New Cross Inn, New Cross	39·90	·114	·417	·004	·420	3215	23·0
Loch Katrine	February, Glasgow	3·28	·256	·031	·002	·041	0	·3
Column 1	2	3	4	5	6	7	8	9

The numbers in columns 3, 4, 5, 6, 7, 8, and 9 all relate to 100,000 parts of the waters. The table is to be read thus: 100,000 lbs. of the Chelsea Company's water collected on 4th March at the Horse Guards' cab rank contained 30·96 lbs. of solid impurity; the organic matter, constituting a portion of this impurity, contained 0·185 lb. of carbon. This solid impurity also contained 0·352 lb. of nitrogen in the form of nitrates and nitrites, besides 0·004 lb. of ammonia, whilst the total amount of *combined* nitrogen in every form was 0·355 lb. The above quantity of water supplied by the Chelsea Company had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 2,565 lbs. of average filtered London sewage. By gradual oxidation, partly in the pores of the soil, partly in the Thames or its tributaries, and partly in the reservoirs, filters, and conduits of the Chelsea Company, this sewage contamination had been entirely converted into comparatively innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of the Chelsea Company's water contained 18·3 lbs. of carbonate of lime, or their equivalent of other soap-destroying ingredients.

The water supplied by the Grand Junction Company has been specially examined for *present sewage contamination* (i.e. sewage existing as such at the time the analysis was made), but it was found to be perfectly free from any such contamination.

All the waters were clear, with the exception of that delivered by the Southwark and Vauxhall Company, which was turbid when drawn from the main.

I have, &c.

The Registrar General, &c. &c. &c.

E. Frankland.

Report for August 1867.

Royal College of Chemistry,
August 27th, 1867.

Sir,

I have the honour to submit to you in the following table the results of the chemical examination of the waters supplied to the metropolis during the month of August. For the purpose of comparison I append also the results yielded by Loch Katrine water, as supplied to Glasgow, when submitted to the same analytical processes.

The numbers in columns 3, 4, 5, 6, 7, 8, and 9 all relate to 100,000 parts of the waters. The table is to be read thus: 100,000 lbs. of Chelsea water collected 1st August at the Horse Guards' cab rank contained 25·65 lbs. of solid impurity; the organic matter, constituting a portion of this impurity, contained ·274 lb. of carbon. This solid impurity also contained ·217 lb. of nitrogen in the form of nitrates and nitrites, besides ·002 lb. of ammonia, whilst the total amount of *combined* nitrogen in every form was ·226 lb. The above quantity of water supplied by the Chelsea Company had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 1,275 lbs. of average filtered London sewage. By gradual oxidation, partly in the pores of the soil, partly in the reservoirs, filters, and conduits of the company, this sewage contamination had been converted into comparatively innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of the Chelsea Company's water contained 18·14 lbs. of carbonate of lime, or an equivalent quantity of other soap-destroying ingredients.

ANALYSIS of the METROPOLITAN WATERS in AUGUST 1867. By Professor FRANKLAND, F.R.S., of the Royal College of Chemistry.

Companies.	Date and Place of Collection.	Total solid Impurity in 100,000 parts.	Organic Carbon.	Nitrogen, as Nitrates and Nitrites.	Ammonia.	Total combined Nitrogen.	Previous Sewage Contamination (estimated).	Total Hardness.

All the waters were clear and transparent when drawn from the companies' mains, except those delivered by the Southwark and Kent Companies. The constant turbidity of the Southwark Company's water indicates some grave defect in their process of filtration. The Kent Company's water had a slightly milky appearance and was filled with light brown floating particles.

I have, &c.
E. FRANKLAND.

The Registrar General,
&c. &c. &c.

The Registrar General, in the body of his Report, remarks on this as follows :—

By Dr. Frankland's analysis of the water supplied by the London companies, it appears that both the New River and the East London waters contained in 100,000 tons 23 tons of extraneous matter, the other companies still more, while the West Middlesex water contained 29 tons and the Kent 40 tons of stuff of various kinds. The previous sewage contamination of all the waters at the time of analysis had apparently been converted into innocuous compounds. By this test the East London waters were then the best, the Chelsea and the Kent waters the worst of the eight. The turbidity of the Southwark water implies some defect in the process of filtration.

The following is the general Report for the whole year 1867 :—

REPORT on the ANALYSIS of the WATERS supplied by the METROPOLITAN WATER COMPANIES during the several Months of the Year 1867, by Professor FRANKLAND, F.R.S., &c.

Royal College of Chemistry.
February 4th, 1868.

SIR,

I HAVE the honour to lay before you a summary of the results of my monthly analytical examinations of the waters supplied to the metropolis during the year 1867. During the past year 105 different samples of water have been submitted to chemical analysis. By new analytical processes devised at the commencement of the year, I have been able in eleven out of the twelve months to obtain determinations of the carbon contained in the organic matters present in the waters, and also to estimate the amount of contamination suffered by each sample from the admixture of sewage or manure matter. In connexion with the opinions now generally entertained with regard to the propagation of certain forms of disease, such as cholera and typhoid fever, by means of spores or germs contained in excrementitious matters, the search for sewage pollution in the metropolitan waters assumes a high degree of importance. The nitrogenous organic matters contained in sewage or manure undergo slow oxidation and conversion into mineral compounds when mixed with water, their carbon is converted into carbonic acid and their hydrogen into water. These products can no longer be identified in the aërated waters of a river, spring, or lake; but the nitrogen of these organic matters is transformed successively into ammonia, nitrous acid, and nitric acid. The two latter combine with bases, and, together with the ammonia, constitute a record of the sewage or other analogous contamination to which the water has been subject. With certain corrections presently to be mentioned, the analytical determination of the nitrogen contained in these mineral compounds furnishes the previous history of the water as regards its contact with decomposing nitrogenous organic matter. In my monthly reports to you during the past year, this determination has been employed for the estimation of the previous sewage contamination of each water, expressed in parts of average filtered London sewage, which, if thus completely oxidized in a river, would yield a like amount of nitrogen in the forms of ammonia, nitrates, and nitrites. For this purpose average filtered London sewage may be taken as containing 10 parts of combined nitrogen in 100,000 parts, as deduced from the numerous analyses of Hofmann and Witt and of Way and Odling. The number so obtained as the previous sewage contamination of a water requires, however, a correction, since rain water itself contains combined nitrogen as ammonia, nitrite of ammonia, and nitrate of ammonia. The amount of these substances present in the rain which falls at Rothampstead has been determined by a series of monthly analyses made independently, on the one hand by Messrs. Lawes and Gilbert, and on the other by Professor

Way, and extending over two years. The results of these chemists give, as the average amount of nitrogen in the forms of ammonia, nitrite of ammonia, and nitrate of ammonia, 0·0985 part in 100,000 parts of rain water. This corresponds to 985 parts of previous sewage contamination, which number was deducted from the previous sewage contamination of the metropolitan waters, as determined by analysis in the months of February to October inclusive. But the experience gained in the examination of numerous samples of water from Wales and Cumberland during the past summer and autumn teaches that this deduction is far too large. The maximum amount of ammonia contained in forty-two such samples of water was only 0·008 part in 100,000, whilst the average amount of nitrogen in the form of nitrous and nitric acid observed by Messrs. Lawes, Gilbert, and Way, and this in thunder-rain only, was but ·024 part in 100,000. It may, therefore, be safely asserted, that the maximum amount of combined nitrogen derived by natural waters from aërial sources does not exceed ·024 + ·008 = ·032 part in 100,000, which gives the number 320 to be deducted from the previous sewage contamination as determined by analysis. In the following tables this number, therefore, has been used throughout in lieu of the number 985, which was employed in my monthly reports from February to October inclusive.

Table A. gives the amount of solid impurity left on evaporation by 100,000 parts by weight of each sample of water.

Table B. the amount of carbon contained in the organic matter constituting a portion of this solid impurity (organic carbon).

Table C. the amount of nitrogen in the form of nitrates and nitrites.

Table D. the amount of ammonia.

Table E. the total quantity of combined nitrogen.

Table F. the amount of previous sewage contamination estimated as above described from Tables D. and E.

Table G. expresses the hardness of each sample of water, that is, the number of parts of carbonate of lime, (or its equivalent of other soap-destroying salts,) contained in 100,000 parts of the water, whilst Table H. exhibits a comparison of the potable waters used in London with those supplied to Romford (by the South Essex Company, whose mains have not yet reached London) and to some other towns.

On referring to Table A. we find that in December 1867, 100,000 lbs. of the water delivered by the Chelsea Company contained 29·8 lbs. of solid impurity. Table B. informs us that the organic matter constituting a portion of this impurity contained ·202 lbs. of carbon; Table C. that ·243 lb. of nitrogen existed in this quantity of the Chelsea water in the form of nitrates and nitrites; Table D. that 100,000 lbs. of this water contain ·002 lb. of ammonia; whilst Table E. shows that it contained a total of ·252 lb. of combined nitrogen in the different forms of organic matter, nitrates, nitrites, and ammonia. Table F. states that 100,000 lbs. of the water had been, after descending as rain, contaminated with sewage or manure matter equivalent to 2,130 lbs. of average filtered London sewage; and Table G. informs us that every 100,000 lbs. of this water contained 21·7 lbs. of carbonate of lime or its equivalent of other hardening salts.

For the purposes of comparison I have also submitted to analysis during the past year the water supplied to the towns of Glasgow, Manchester, Lancaster, and Leicester, and to the metropolitan suburb of Romford. The results of these analyses are compared in Table H. with the mean results of the analysis of the metropolitan waters during the year. The last column of this table also shows the number of lbs. of good hard soap which would be destroyed by 100,000 lbs. of each water used for washing, before any useful detergent effect would be produced.

When compared with the tables given in my last annual report the following analytical results show that the water delivered by the Chelsea, West Middlesex, Southwark, East London, and Kent companies was softer than in 1866, the New River Company's water had exactly the same mean hardness in both years, whilst that delivered by the Grand Junction and Lambeth companies was slightly harder in 1867 than in 1866

The total solid impurity exhibits an increase over 1866 in every case except that of the East London Company, in which a marked decrease has occurred. In former years the quality of this latter company's water was inferior to that of the remaining metropolitan supply, but it has been so much improved during the past year that this water is now only inferior to the supply distributed by the New River Company.

Considering the great previous sewage contamination exhibited by the river waters supplied to London, it is much to be regretted that these waters are not more effectively filtered before distribution. Only on one occasion during the whole year have I obtained a transparent sample of water from the Southwark Company's mains. The Grand Junction and Kent Company's waters were turbid four times out of twelve, the Chelsea thrice, and the West Middlesex, Lambeth, and East London each twice out of the twelve occasions when the samples were drawn for analysis. The New River Company stands alone in the perfection of its filtering apparatus; on no occasion during the past year has this company's water exhibited the slightest turbidity, thus proving that perfect filtration is compatible with the largest daily supply furnished by any one company in London. The seven companies, who occasionally or habitually send out turbid water, subject the inhabitants of more than 300,000 houses to the unnecessary expense of private filtration.

The distribution of water in the metropolis still continues, with but slight exceptions, upon the intermittent system, which has been abolished in almost every other town of importance in the United Kingdom. In addition to the well-known evils attending the storage of water in butts and cisterns under this system, there is the danger of the leakage of sewage into the pipes whilst the pressure is withdrawn. An instructive instance of this occurred in the West Middlesex Company's district in June last. The water drawn from this company's main on the 1st June was found on analysis to contain rather more than one per cent. of fresh sewage. In answer to my inquiries the company's engineer informed me that a leakage had occurred in one of the mains near a gullyhole. This fracture, which was repaired on the 3d of June soon after its discovery, occurred to a main from which the water pressure was removed at night, and there can be little doubt that during the absence of the internal pressure sewage gained access to the interior of the main. It is only right to add that, with the exception of this accidental contamination, and one other instance of slight turbidity, the water distributed by the West Middlesex Company has been of as great a degree of purity as it is possible to attain in water derived from the Thames at Teddington.

I have, &c.
E. FRANKLAND.

The Registrar General,
&c. &c. &c.

Columns	1	2	3	4	5

Note.—According to returns of the London Water Companies made to the Select Committee on East London Water Bills (Session 1867), it is estimated that on an average, during the year 1866, about 80 per cent. of the total average daily supply of water for all purposes was for domestic use; the proportions supplied for the year 1866 have been applied in estimating the quantities for the year 1867 in column 4, showing the cubic metres probably used for domestic purposes.

The average daily quantity of water supplied by the London Companies during the year 1867 was 98,600,248 gallons (447,985 cubic metres, equal to about as many *tuns* by measure, *tons* by weight), of which about 81,555,056 gallons (370,542 cubic metres) were probably used for domestic purposes. The quantity used for house supply daily was 839 litres to each house, and 120 litres (=26·5 gallons) to each person.

* A cubic metre is equal in volume to 35·3174 cubic feet, or to 220·0967 imperial gallons. It is nearly equivalent to the old English *tun* of four hogsheads, holding 35·248 cubic feet. It is in general use on the Continent; and its volume of water weighs a metric ton, differing inconsiderably in weight from the ton in common use.

† 4·543458 litres equal one gallon.

‡ The quantities of water in columns 2 and 3 include the supply for manufactures and for various purposes other than for domestic consumption.

REPORT for January 1868.

Royal College of Chemistry,
January 31st, 1868.

SIR,

I HAVE the honour to submit to you in the following Table the results of the chemical examination of the waters supplied to the metropolis during the month of January. For the purpose of comparison I append also the results yielded by Loch Katrine water, as supplied to Glasgow, and by waters supplied to the towns of Lancaster, Manchester, Leicester, and Preston, when submitted to the same analytical processes.

The numbers in columns 4, 5, 6, 7, 8, 9, 10, and 11 all relate to 100,000 parts of the waters. The table is to be read thus: the Chelsea Company's water collected on 21st January at the Horse Guards' cab rank had a temperature of 7·2 C., it contained 29·2 lbs. of solid impurity; the organic matter, constituting a portion of this impurity, contained ·353 lb. of carbon and ·058 lb. nitrogen. This solid impurity also contained ·339 lb. of nitrogen in the form of nitrates and nitrites, besides ·001 lb. of ammonia, whilst the total amount of *combined* nitrogen in every form was ·339 lb. The above quantity of water supplied by the Chelsea Company had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 3,080 lbs. of average filtered London sewage. By gradual oxidation, partly in the pores of the soil, partly in the Thames and its tributaries, and partly in the reservoirs, filters, and conduits of the company, this sewage contamination had been converted into comparatively innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of the Chelsea Company's water contained 15·4 lbs. of carbonate of lime, or an equivalent quantity of other soap-destroying ingredients.

The waters delivered in London during the latter part of January by the Chelsea, and especially by the Southwark and Lambeth companies, were in such a muddy condition as to render them totally unfit for domestic use. The Thames has overflowed its banks above the point at which the water supply is withdrawn, and by washing the surfaces of cultivated fields and mingling with the contents of stagnant ditches and ponds has become contaminated to an intolerable degree. Those companies which, like the West Middlesex and Grand Junction, possess ample and efficient filtering apparatus, were enabled so far to cope with the difficulty as to send out their supply free from suspended matters. A week later, however, than the date when the samples were collected, the water of the Grand Junction Company had also become turbid, but much less so than that delivered by the Southwark and Lambeth companies. It will be seen from a reference to the analytical tables that the Thames was contaminated at the time the samples were taken with double the usual proportion of organic matter. Besides dissolving the soluble manure matters from cultivated fields, the recent heavy rains flushed the sewers of Oxford, Windsor, &c., dislodging great quantities of putrescent animal matters and sweeping them into the Thames: hence the large proportion of organic carbon and nitrogen, and the great previous sewage contamination in the waters of those companies which derive their supply from that river. The West Middlesex Company's water, though well filtered and perfectly transparent, had been thus contaminated to an extent which would be produced by the admixture of one-third of a gallon of average filtered London sewage with each ten gallons of the water. The River Lea also exhibits a very high previous sewage contamination, but at the time when the New River and East London companies' samples were collected it had not been affected like the Thames, for, although the East London water was full of suspended brown particles, the analyses of these waters show that the organic carbon and nitrogen are remarkably low for the season. The Kent Company's water was slightly turbid from yellow particles.

I have, &c.
E. FRANKLAND.

The Registrar General,

REPORT for February 1868.

Royal College of Chemistry,
SIR, February 29th, 1868.

I HAVE the honour to submit to you in the following table the results of the chemical examination of the waters supplied to the metropolis during the month of February. For the purpose of comparison I append also the results yielded by Loch Katrine water, as supplied to Glasgow, and by the waters supplied to the towns of Lancaster, Manchester, Leicester, Preston, and Worthing, when submitted to the same analytical processes.

The waters delivered by the New River, East London, and Kent companies were clear and transparent, but, with the exception of the West Middlesex, all the companies drawing their supply from the Thames were delivering imperfectly filtered water on the day when the samples were taken. The Lambeth Company's water was so muddy that brightly illuminated objects could not be seen through a stratum of it 12 inches deep. The Chelsea Company's water was but little better in this respect, and the supply of both companies was, on this ground alone, entirely unfit for domestic use. The water delivered by the Southwark and Grand Junction companies was only slightly turbid.

The organic matter contained in all the samples of water, except those of the West Middlesex and Southwark companies, was highly nitrogenized, and therefore probably of animal origin to a considerable extent.

The condition of the Kent Company's water delivered at the Deptford Railway Station on the 7th inst. presented remarkable peculiarities. It contained the very large amount of 59·2 parts of solid impurity in 100,000 parts of the water, 42 parts being the maximum and 39·3 the mean amount observed in this company's water during the year 1867. Of the above 59·2 parts no less than 14·7 were common salt, the occurrence of which in such quantity is difficult to account for, except on the supposition that the company's wells have some connexion either with the sea or the brackish reaches of the Thames. The previous sewage contamination was also higher than that observed on any former occasion.

For the first time since February 1867 the East London Company's water exceeds that of the New River Company in previous sewage contamination.

I have, &c.
E. FRANKLAND.

The Registrar General,

* In the last month's report through a clerical error the total combined nitrogen in the Chelsea Company's water was given as ·339 instead of ·398.

The numbers in columns 4, 5, 6, 7, 8, 9, 10, and 11 all relate to 100,000 parts of the waters. The table is to be read thus: the Chelsea Company's water collected on 4th February at the Horse Guards' cab rank had a temperature of 7·2° C.; 100,000 lbs. of it contained 30·8 lbs. of solid impurity; the organic matter, constituting a portion of this impurity, contained ·326 lb. of carbon and ·052 lb. of nitrogen. This solid impurity also contained ·340 lb. of nitrogen in the form of nitrates and nitrites, besides ·002 lb. of ammonia, whilst the total amount of *combined* nitrogen in every form was ·394 lb. The above quantity of water supplied by the Chelsea Company had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 3,100 lbs. of average filtered London sewage. By gradual oxidation, partly in the pores of the soil, partly in the Thames and its tributaries, and partly in the reservoirs, filters, and conduits of the company, this sewage contamination had been converted into innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of the Chelsea Company's water contained 18·8 lbs. of carbonate of lime, or an equivalent quantity of other soap-destroying ingredients.

REPORT for June 1868.

Royal College of Chemistry,
June 25th, 1868.

SIR,

I HAVE the honour to submit to you in the following table the results of the chemical examination of the waters supplied to the metropolis during the month of June. For the purpose of comparison I append also the results yielded by Loch Katrine water, as supplied to Glasgow, and by the waters supplied to the towns of Lancaster, Manchester, Leicester, Preston, and Worthing, when submitted to the same analytical processes.

The long-continued drought has rendered the river waters supplied to London unusually pure. The previous sewage contamination of these waters is on the average much lower than has ever before been observed.

The Southwark Company's water was again turbid from the presence of much suspended matter; besides giving the water a repulsive appearance, this suspended matter is nitrogenous, and therefore highly objectionable. With the exception of the East London Company's water, which contained, however, only traces of suspended matter, the rest of the samples were perfectly bright and transparent.

I have, &c.,

The Registrar General, &c. &c. &c.

E. FRANKLAND.

ANALYSIS of the METROPOLITAN WATERS in JUNE 1868. By Professor FRANKLAND, F.R.S., of the Royal College of Chemistry.

Column 1	2	3	4	5	6	7	8	9	10	11

The numbers in columns 4, 5, 6, 7, 8, 9, 10, and 11 all relate to 100,000 parts of the waters. The table is to be read thus: the Chelsea Company's water collected on 18th inst. at the Horse Guards' cab rank had a temperature of 19·1° C., 100,000 lbs. of it contained 29·4 lbs. of solid impurity; the organic matter, constituting a portion of this impurity, contained ·148 lb. of carbon and ·018 lb. of nitrogen. This solid impurity also contained ·113 lb. of nitrogen in the form of nitrates and nitrites, besides ·002 lb. of ammonia, whilst the total amount of *combined* nitrogen in every form was ·133 lb. The above quantity of water supplied by the Chelsea Company had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 820 lbs. of average filtered London sewage.

By gradual oxidation, partly in the pores of the soil, partly in the Thames and its tributaries, and partly in the reservoirs, filters, and conduits of the company, this sewage contamination had been converted into innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of the Chelsea Company's water contained 19·7 lbs. of carbonate of lime, or an equivalent quantity of other soap-destroying ingredients.

The following is the Report for the whole year 1868:—

REPORT on the ANALYSIS of the WATERS supplied by the METROPOLITAN WATER COMPANIES during the several MONTHS of the YEAR 1868, by PROFESSOR FRANKLAND, F.R.S., &c.

Royal College of Chemistry,
January 28th, 1869.

SIR,

IN the accompanying tables I have the honour to submit to you a summary of the results of my analytical examinations of the waters supplied to the metropolis, to Edinburgh, and to certain provincial towns during the year 1868. The analytical methods which I began to employ in the previous year have been continued, and I have the satisfaction to find, that an experience extending to more than 700 different samples of water, from the most widely different sources in Great Britain, has only served to confirm my confidence in the new processes of analysis to which the metropolitan waters have, for the past two years, been submitted.

Table A. shows the temperature of the different waters as delivered from the companies' mains on the days when the samples were taken.

Table B. the amount of solid impurity left on the evaporation of 100,000 parts by weight of each sample.

Table C. the amount of carbon contained in the organic matter constituting a portion of this solid impurity (organic carbon).

Table D. the amount of nitrogen contained in the organic matter (organic nitrogen).

Table E. the amount of ammonia.

Table F. the amount of nitrogen in the form of nitrates and nitrites.

Table G. the total quantity of combined nitrogen.

Table H. the amount of previous sewage or manure contamination deduced from the amount of nitrogen in the form of nitrates, nitrites, and ammonia in excess of that contained in rain water in these forms. Nitrogenous organic matter *of animal origin* (such as that contained in the liquid and solid excrements of animals), when present in water or in the soil through which water percolates, undergoes gradual oxidation, its nitrogen becoming converted into ammonia, nitrous acid, and nitric acid, which remain in the water and constitute a record of previous sewage or manure contamination. In undergoing a similar decomposition, *vegetable* organic matter has never been observed to yield these products. I have sought for them in vain in scores of samples of water heavily contaminated with vegetable organic matter, and

taken from both springs, rivers, and surface drains. But rain-water generally contains minute traces of them amounting in the maximum to ·032 part of nitrogen in all these forms in 100,000 parts of rain-water. It is necessary therefore to deduct this amount from that found in the analysis of a sample of potable water. If there is any remainder, the water stands convicted of having been in contact with decaying animal matter. For sanitary purposes all forms of decaying animal substances may be classed as either sewage or manure matters, and all waters which have been in contact with an appreciable quantity of substances belonging to either category ought, if possible, to be rejected for domestic supply. To express this kind of contamination in terms of some known standard, I employ average filtered and fresh London sewage, which contains 10 parts of nitrogen, in the form of animal organic nitrogen, in 100,000 parts. Thus a water which yields on analysis 1·032 part of nitrogen in 100,000, as nitrous acid, nitric acid, and ammonia, contains, in 100,000 parts, the nitrogenous remains or skeleton of an amount of animal organic matter equal to that contained in 10,000 parts of average fresh filtered London sewage. Such a water is therefore said to have a previous sewage or manure contamination of 10,000 parts in every 100,000 parts.

Table I. expresses the hardness of each sample of water, that is, the number of parts of carbonate of lime (or its equivalent of other soap-destroying salts) contained in 100,000 parts of the water.

Table K. exhibits a comparison of the potable waters used in London with those supplied to Edinburgh, and some provincial towns.

The tables are to be read thus:—According to Table A., the water delivered by the Chelsea Company in January had a temperature of 7·2° Centigrade; Table B. states that 100,000 lbs. of this water contained 29·2 lbs. of solid impurity; Table C. informs us that the organic matter constituting a portion of this impurity contained ·353 lb. of carbon; Table D. that this organic matter also contained ·058 lb. of nitrogen; Table E. that 100,000 lbs. of this water contained ·001 lb. of ammonia; Table F. that ·339 lb. of nitrogen existed in the same weight of water as nitrates and nitrites; whilst Table G. shows that it contained a total of ·398 lb. of combined nitrogen in the different forms of organic matter, nitrates, nitrites, and ammonia. Table H. states that 100,000 lbs. of the water had been, after reaching the earth as rain, contaminated with sewage or manure matter equivalent to 3,080 lbs. of average filtered London sewage; and Table I. informs us that every 100,000 lbs. of this water contained 15·4 lbs. of carbonate of lime or its equivalent of other hardening salts.

The past year was distinguished by very heavy floods in the Thames basin in the winter, followed by excessive drought in summer. It was therefore to be expected that the quality of the waters of the Thames and the Lea would vary between limits unusually wide. An inspection of the accompanying analytical results shows this to have been the case. Thus the total solid impurity in Thames water varied from 22·6 to 38·6 parts in 100,000, whilst that in the Lea water ranged from 21·2 to 36 parts in 100,000. In January the Thames overflowed its banks above the point at which the metropolitan water supply is drawn, and washing the surfaces of cultivated fields, mingling with the stagnant ditches and ponds, and receiving the contents of the suddenly flushed sewers of Oxford, Reading, and Windsor, became contaminated to an intolerable degree, as evidenced by the unusually large proportion of organic carbon, organic nitrogen, and previous sewage contamination in the waters of those companies which draw from that river. It is remarkable that the quality of the water supplied from the Lea by the New River and the East London companies was but slightly affected by this flood.

On the other hand, in the summer months the waters of both rivers attained a degree of purity which I have never before observed in them. The excessive drought prevented much animal matter, both solid and liquid, from reaching the streams. The refuse was absorbed into the thirsty soil, whence it was afterwards partially dislodged by the heavy rains of October and December.

It has been frequently asserted, but without proof, that the noxious organic matter of sewage, when discharged into a river of considerable magnitude, is entirely destroyed by oxidation after a flow of a few miles. This assertion is erroneous. In his evidence before the Rivers Pollution Commission, Sir Benjamin Brodie says (First Report of Rivers Pollution Commission; Minutes of Evidence, p. 49), "I "should say that it was simply impossible, that the oxidizing power acting on sewage running in mixture with "water over a distance of any length is sufficient to remove "its noxious quality. Taking the case of Oxford, if the "sewage of Oxford was, in its entirety, discharged into the "river Thames, I should say that we could certainly not trust "to the oxidizing power to take away the noxious quality "of the water before it reaches, say, Teddington I presume "that the sewage could only come in contact with oxygen "from the oxygen contained in the water, and also from the "oxygen on the surface of the water, and we are aware that "ordinary oxygen does not exercise any rapidly oxidizing "power on organic matter. I believe that an infinitesimally "small quantity of decaying matter is able to produce an "injurious effect upon health. Therefore, if a large proportion of organic matter was removed by the process of "oxidation, the quantity left might be quite sufficient to "be injurious to health. With regard to the oxidation, we "know that to destroy organic matter the most powerful "oxidizing agents are required, we must boil it with nitric "acid and chloric acid, and the most perfect chemical agents. "To think to get rid of organic matter by exposure to the "air for a short time is absurd."

My analyses of Thames water delivered in London during the past year completely confirm Sir B. Brodie's opinion. They leave no doubt that, although oxidation does take place to some extent, a considerable proportion of the animal organic matter contained in the sewage of Oxford, Reading, Windsor, &c. reaches Teddington in an unoxidized condition.

When compared with the mean analytical results of 1867, the numbers obtained in 1868 show that the water delivered by the Chelsea, West Middlesex, Grand Junction, Lambeth, and East London companies contained slightly less solid impurity in 1868, that delivered by the New River Company contained a slight excess in 1868 (·42 part in 100,000), whilst the Southwark and Kent companies' waters exhibited a considerable increase, amounting to 2·55 and 6·03 parts respectively in 100,000. With the exception of the Lambeth, all the companies delivered water containing a greater maximum amount of solid impurity in 1868 than in 1867. The maximum amount of solid impurity in the Lambeth Company's water was the same in both years.

In every case except one the mean amount of organic carbon was much less in the past than in the previous year; the Southwark Company's water constitutes the exception; it contained only ·003 part in 100,000 less in 1868 than in 1867.

The following table exhibits a comparison of the previous sewage or manure contamination of the different waters in the two years:—

	1867.			1868.		
Thames.	Maximum.	Minimum.	Mean.	Maximum.	Minimum.	Mean.
Chelsea	3,230	1,570	2,107	3,451	350	1,858
W. Middlesex	3,290	1,050	2,069	3,360	110	1,590
Southwark	3,290	1,130	1,953	3,130	150	1,742
Grand Junction	3,160	1,050	2,036	3,340	330	1,811
Lambeth	3,150	1,260	2,144	4,050	520	1,992
Other Sources.						
New River	3,200	1,290	2,192	3,300	140	1,754
East London	3,280	230	1,610	3,400	0	1,148
Kent	4,820	2,890	3,619	5,330	3,540	3,842

The higher numbers in this table occurred in the winter, the lower in the summer months, the summer numbers being exceptionally low during the past year, owing partly to the activity of aquatic vegetation in purifying the water, and partly to the long drought, which prevented much filth from being washed into the Thames and Lea for many months.

The mean hardness of all the waters delivered in London during 1868 was greater than during 1867, with the exception of that of the Lambeth Company's water, which was 1·7° less in 1868. On the average the water delivered to consumers during the past year was nearly 1° harder than that supplied during the previous year.

I have again to call your attention to the very inefficient filtration of a considerable proportion of the water supplied to the metropolis. On several occasions the water of the Lambeth, Southwark, and Chelsea companies was in such a muddy condition as to render it totally unfit for domestic use. In February last the Lambeth Company's water was so turbid that brightly illuminated objects could not be seen through a stratum of it 12 inches deep. On account of the great amount of sewage which commingles with the river waters supplied to London, their efficient filtration before delivery is of the utmost importance.

How far this is actually accomplished by the different companies may be seen from the following table, showing the condition of the various samples when drawn from the companies' mains:—

	Number of Occasions when clear and transparent.	Number of Occasions when slightly turbid.	Number of Occasions when turbid.	Number of Occasions when very turbid.
THAMES.				
Chelsea - -	7	2	1	2
W. Middlesex -	12	0	0	0
Southwark - -	1	5	4	2
Grand Junction -	9	2	1	0
Lambeth - -	6	1	2	3
OTHER SOURCES.				
New River - -	10	2	0	0
E. London - -	3	8	1	0
Kent - - -	8	3	1	0

Of all the companies supplying London with water, the West Middlesex stands pre-eminent as regards careful filtration; not even during the early part of the year, when the Thames was excessively muddy from floods, did this company on any occasion send out water which was not perfectly clear and transparent. An inspection of Table K. shows that in other respects also the West Middlesex Company's water was superior to that of every other company drawing from the Thames. It is thus evident, that with efficient filtration Thames water can be delivered to consumers clear and transparent, even in the most unfavourable seasons.

The New River and Grand Junction companies stand next in regard to efficient filtration, whilst the Southwark Company's water is almost invariably sent out in an imperfectly filtered condition. Only on one occasion in the entire year did I obtain a sample of clear water from this company's mains, and the same was the case in 1867.

During the year the water delivered by two of the metropolitan companies exhibited for a time an exceptionally high degree of contamination. The first case was that of the Kent Company's water, which, in February and March, presented remarkable peculiarities. In February it contained no less than 59·2 parts of solid impurity in the 100,000 parts, 42 parts being the maximum and 39·3 the mean amount observed during the year 1867. Of the above 59·2 parts, 14·7 were common salt, the occurrence of which in such quantity is difficult to account for without assuming contamination from a tidal river. In March the condition of things was much worse, for the solid impurity had increased to 70·2 parts, and the common salt to 23·7 parts. The attention of the company's engineer was strongly drawn to this abnormal state of the water, and in the following month the excess of impurity disappeared.

The company's works are situated close to and on both sides of the river Ravensbourne, from which a considerable portion of the supply was formerly derived. The old reservoirs and filter beds, occupying a large area of land, sunk below the level of the Ravensbourne, are still retained, and one of them at least is used for the temporary storage of a portion of the water raised from the company's wells. The position of these reservoirs must render it very difficult to exclude percolation from the foul river, which runs within a few yards of them for a considerable distance. The remark which you made in 1866, in reference to a very similar state of things then existing at the Old Ford station of the East London Water Company, is applicable with equal force to the Kent Company's works at Deptford.

In the interests of the public health, the country has a right to demand the security which could be afforded by the filling up, and conversion into valuable land, of these old reservoirs, which the company admits are of little or no use.

The second case of exceptional contamination occurred to the Southwark Company's water during the months of August, September, and October. Drawing its supply from the same source as the other Thames companies, the Southwark Company delivered, during these months, water of a strikingly different composition. A reference to the accompanying tables B., C., and D., shows that the total solid impurity, and (in September and October) the organic constituents, were in very marked excess in this as compared with the remaining Thames waters. The proportion of common salt in Thames water delivered by the other companies during the three months above mentioned never exceeded 3·6 lbs. in 100,000 lbs. of water; whilst in the Southwark Company's water it was as follows: in August 7·5 lbs., in September 13·6 lbs., and in October 7·2 lbs. I directed the attention of the company's engineer to this abnormal condition of the water, pointing out that the admission of a certain proportion of tidal water of the Thames at Battersea, where the company's reservoirs are situated close to the river, would cause the excess of the impurities which I had observed. The exceptional contamination had been prevented when the November sample was taken, and it has not since recurred. These instances show the great importance of the analytical determination of common salt or of chloride in the London waters. Many of the companies' reservoirs are placed below high-water mark, on the banks of tidal rivers, and are, therefore, liable to percolations from the neighbouring streams, whence they formerly received their supply of water. I have, therefore, since October last added determinations of chloride to the other analytical results, and propose to continue them in my future monthly reports.

I have, &c.

The Registrar General, &c. &c. &c.

E. FRANKLAND.

Columns	1	2	3	4	5

Note.—According to returns of the London Water Companies made to the Select Committee on East London Water Bills (Session 1867), it is estimated that during the year 1866, on an average, 82·18 per cent. of the total average daily supply of water for all purposes was for domestic use; the proportions supplied for the year 1866 have been applied in estimating the quantities for the year 1868 in column 4, showing the cubic metres probably used for domestic purposes.

The average daily quantity of water supplied by the London Companies during the year 1868 was 99,892,311 gallons (453,857 cubic metres, equal to about as many *tuns* by measure, *tons* by weight), of which about 82,095,838 gallons (373,000 cubic metres) were probably used for domestic purposes. The quantity used for house supply daily was 82·3 decalitres to each house, and 11·6 decalitres (=25·53 gallons) to each person.

* A cubic metre is equal in volume to 35·3174 cubic feet, or to 220·0967 imperial gallons. It is nearly equivalent to the old English *tun* of four hogsheads, holding 35·248 cubic feet. It is in general use on the Continent; and its volume of water weighs a metric ton, differing inconsiderably in weight from the ton in common use.

† One gallon equals ·4543458 of a decalitre.

‡ The quantities of water in columns 2 and 3 include the supply for manufactures and for various purposes other than for domestic consumption.

The water companies in their returns reckon uninhabited as well as inhabited houses.

APPENDIX AK.

REPORT from PROFESSOR WANKLYN, on the QUALITY of the WATER supplied in the METROPOLIS.

London Institution,
June 20, 1868.

SIR,

THE result of a prolonged examination carried out by myself, Mr. Chapman, and Mr. Smith, on the Water Supply of London, Manchester, Glasgow, and Edinburgh, last summer, is the following:—

The water of the Thames at Hampton Court, where the Companies draw their supply of Water, is not very good, as it exists in the river; but after the filtration effected by *some* (but not all) of the Companies, it becomes excellent, and in point of purity from organic nitrogenous matter is then fully equal to the water supplied to Manchester, Edinburgh, or Glasgow.

The water supplied by the New River Company is also very good.

Very truly yours,

W. Pole, Esq. (Signed) J. A. WANKLYN.

PARTICULARS of WATER SUPPLIES to various PROVINCIAL TOWNS.

APPENDIX AM.

PARTICULARS of WATER SUPPLIES to various

Name of Town.	Population in 1861.	Source of Supply.	Whether supplied by Gravitation or Pumping.	Area of Gathering Ground (if any).	Whether Constant or Intermittent Supply.	Whether Works in hands of Private Company or Corporation.
Nottingham	130,000	Chief supply from wells in red sandstone, and part from River Trent by natural filtration.	First pumped, then by gravitation; part supplied from main on way to reservoir.	- -	Constant -	Private company
Bristol -	116,280	Springs at Chewton, Mendip, Harptree Combe, and Barrow Gurney, and from River Kenn at Chelvey.	Gravitation; a small portion pumped 140 feet to elevated reservoir for service of high ground at Clifton, &c. Auxiliary supply pumped from River Kenn to gravitation reservoirs, 350 feet high.	- -	Constant, with power to shut off.	Private company
Preston -	82,262	Collecting ground at Longridge.	Gravitation - -	- -	Constant -	Corporation -
Dundee -	90,000	Surface collection - -	Gravitation - -	- -	Constant -	Private company
Norwich -	53,000	River Wensom - -	First pumped, then by gravitation; small part supplied from main on way to reservoir.	- -	Constant -	Private company
Leicester -	52,420	Thornton watershed -	Gravitation -	- -	Constant -	Private company
Derby -	37,496	Springs from sandstone, and water from River Derwent obtained by natural filtration.	First pumped, and then by gravitation.	- -	Constant -	Private company
Croydon -	29,838	Wells in the chalk - -	First pumped, and then by gravitation; but town is partly supplied from main on way to reservoir.	- -	Intermittent, on 11 hours out of 24.	Local Board of Health.
Liverpool -	600,000	Wells and impounded water, the former in the immediate neighbourhood of Liverpool, and the latter at a distance from 24 to 31 miles.	Gravitation and pumping from wells to reservoirs, thence by gravitation.	- -	Intermittent on 15 hours, off 9 hours.	Corporation -
Glasgow -	490,308	Loch Katrine and the Gorbals	Gravitation - -	- -	Constant -	Corporation -
Manchester	459,968	Collecting grounds and mountain springs at Woodhead, and the River Etheron near its rise.	Gravitation - -	- -	Constant -	Corporation -
Leeds -	222,240	Collecting grounds at Eccup, and pumping from River Wharfe.	Part gravitation, part pumping into reservoirs; then by gravitation to town.	- -	Constant -	Corporation -
Edinburgh	202,185	Collecting grounds on the Pentland Hills, and springs at Crawley and other places.	Gravitation - -	- -	Constant -	Private company
Sheffield -	198,850	Off the moors at Redmires. New source, Loxley watershed.	Gravitation - -	- -	Intermittent, 12 hours per day.	Private company
Newcastle-on-Tyne.	160,000	Collecting grounds and streams at Hallington and Whittle Dean, and water is also pumped at Newburn from the Tyne.	Part gravitation, part pumped into reservoirs.	- -	Constant -	Private company
Sunderland and South Shields.	150,000	Wells - - -	Pumped into reservoir, then gravitation.	- -	Constant -	Private company

APPENDIX AX. (1.)

Preliminary Report from Drs. Frankland and Odling on the Waters of the Thames Basin.

College of Chemistry,
Oxford Street, July 13, 1868.

Sir,

Herewith we send you the results of our partial analyses of all the samples of water submitted to us by the Royal Commission on Water Supply. From the extended character of the investigation, as well as in some degree from the pressure of other engagements, we regret that we are not as yet able to furnish you with our complete results, but we expect to be able to let you have them very shortly.

Our results so far as they have gone lead to the following conclusions:—

1. The head waters of the Thames closely resemble the waters obtained from chalk springs and borings at Watford, Amwell, and other places in the Thames Basin. They are hard, but free to a remarkable extent from organic matter.

2. The water of the Thames within half a mile below Lechlade does not differ substantially from that of the Thames at Hampton; but the amount of organic matter contained in the water of the river at these two points is about eight times that contained in the head waters.

3. Nowhere between Lechlade and Hampton do we find the water of the Thames more pure than at these two points, while at many intermediate points, notably below Reading, it is much less pure.

4. We have not found the water of any tributary to the Thames below Lechlade, that we have examined, preferable to the water of the Thames at Hampton for the purposes of town supply.

5. Our examination of the series of samples illustrating the purification of the sewage of Croydon by its passage over cultivated land shows the very great advantage which may follow the adoption of this process. But we think it right to observe that the extreme degree of improvement indicated by our results in that particular set of experiments is in considerable excess of the degree of improvement which we have observed on other occasions, although this also is very marked.

Regretting much our inability, at the present moment, to let the Commission have our complete results and report,

We are, &c.,
E. Frankland.
W. Odling.

To William Pole, Esq., F.R.S.

APPENDIX AX. (2.)

Report on the Chemical Quality of Samples of Water collected in the Basin of the Thames. By Dr. E. Frankland, F.R.S., and Dr. Odling, F.R.S.

To the Royal Commission on Water Supply.

My Lord Duke and Gentlemen,

Having been intrusted by you with the chemical analysis of a number of samples of water, collected by Mr. William Pole, F.R.S., from the River Thames and its tributaries, and from artesian wells in the chalk, we have now the honour to submit to you the results of our examination.

The samples were selected apparently with a view to ascertain—

1st. The chemical character of the principal feeders of the Thames, and of the water obtained by artesian borings in the chalk.

2nd. The change in the chemical character of Thames water consequent on its flow through a populous district.

3rd. The extent to which town sewage can be purified by its passage over or through land under the process of irrigation.

The following table contains a list of the samples transmitted to us by Mr. Pole, the dates of their collection, and our remarks on the appearance of the samples when seen in a quart decanter.

Place of collection.	Date of collection.	Appearance of samples.
Syrefords Spring (Lower Oolite)	1868.	
Thames Head Well (Upper Oolite)	March 18th*	Clear and colourless.
Ampney Park Springs (Upper Oolite), and Boxwell Spring (Upper Oolite) mixed	April 18th	Clear and colourless.
Thames at St. John's Bridge, below Lechlade.		
Thames at Midley Lock, above Oxford.	„ 29th	Turbid and yellowish.
River Cherwell, above Oxford.	„ 29th	Turbid and very slightly yellow.
Thames at the Gut below Oxford.	„ 29th	Turbid, greenish yellow.
Thames at the Weir above Abingdon.	„ 30th	Turbid, very slightly yellow.
River Thame, just before junction.	„ 30th	Clear and colourless.
Thames at Caversham Bridge, above Reading.	„ 24th	Turbid, yellowish.
River Kennet, above Hungerford.	„ 20th	Clear and colourless.
River Kennet, just above Reading.	„ 24th	Turbid, slightly greenish yellow.
Thames, just below Reading.	„ 24th	Very turbid, yellow.
Thames at Shiplake, 5 miles below Reading.	„ 25th	Turbid, greenish yellow.
Thames at Medmenham	April 25th	Turbid, yellowish.
Thames, just above Windsor.	May 2nd	Turbid, slightly yellow.
Thames, 2 miles below Windsor sewers outfall.	„ 2nd	Turbid, yellowish.
Thames, above Staines	„ 2nd	Turbid, slightly yellow.
River Wey, above Godalming.	April 21st	Clear, slightly greenish yellow.
Thames at Water Companies intake at Hampton.	May 4th	Very slightly turbid, faint yellow tint.
River Mole	„ 4th	Turbid, yellowish.
River Loddon on Bagshot Sands.	April 21st	Clear, deep brownish yellow.
Mimram and Lee mixed	May 5th	Very turbid, yellowish.
Amwell Well	„ 5th	Clear and colourless.
Otter's Pool Spring, Watford.	April 8th	Clear and colourless.
Artesian Well at Caterham.	May 12th	Clear and colourless.
Artesian Well at Croydon.	„ 11th	Clear and colourless.
Croydon sewage as it flows upon land.	„ 11th	Very turbid and semi-opaque.
Croydon sewage as it flows off land.	„ 11th	Turbid, greenish yellow.
River Wandle, about 3 furlongs below the point where the purified sewage enters.	„ 11th	Very slightly turbid, colourless, many cysts and animalculæ.
River Wandle at Mitcham.	„ 11th	Slightly turbid, colourless, some animalculæ.

* Should be April 18th.—W. Pole.

The analyses were conducted in the manner already described in our report on the samples collected in North Wales and in the Lake District of Cumberland and Westmoreland. The following tables are to be read in the manner there described.

The waters of wells, of springs, and of streams near their sources, were submitted by us to analysis after subsidence but without filtration; since these waters would not necessarily require filtration before being supplied to a community. On the other hand, as the river waters would necessarily have to be filtered before being used for water supply, we considered that our results would, in these cases, be more instructive if obtained from water which we had previously filtered.

We have, &c.,
E. Frankland.
Wm. Odling.

Additional Observations by Dr. Frankland.

The above analytical results suggest the following observations in connexion with the three objects of the inquiry already mentioned, viz.:—1st. The chemical character of the principal feeders of the Thames, and of the water obtained by artesian borings in the chalk; 2nd. The change in the chemical character of Thames water during its flow through a populous district; and 3rd, the extent to which town sewage can be purified by its passage over or through land in the process of irrigation.

I. *Chemical Character of the principal Feeders of the Thames, and of the Water obtained by Artesian Borings in the Chalk.*

The mixed samples of the five chief head springs in the oolite forming the source of the Thames present a water pleasant to the eye and to the palate. Although this water has drained through cultivated and pasture land, its passage through the oolite has almost completely deprived it of the organic matter with which it was at first doubtless contaminated; the same remark applies also to all the samples of water from chalk springs and wells, as seen from the following table:—

	Organic carbon in 100,000 parts of water.	Organic nitrogen in 100,000 parts of water.
Head Springs of Thames -	·014	·009
Amwell Well - - -	·076	·009
Otter's Pool Spring, Watford -	·026	·012
Artesian Well at Caterham -	·020	·006
„ „ Croydon -	·040	·007
„ „ Deptford* -	·053	·006
„ „ Bromley† -	·033	·008

It is worthy of remark that, although the amount of organic matter in these waters is very small, it is highly nitrogenized.

With the sole exception of the Caterham water, all the samples exhibit a high previous sewage contamination, as seen from the following table:—

	Previous sewage contamination in 100,000 parts.
Head Springs of Thames - - -	3,260
Amwell Well - - -	3,740
Otter's Spring, Watford - - -	3,920
Artesian Well at Caterham - -	0
„ „ Croydon - -	5,200
„ „ Deptford - -	3,540
„ „ Bromley - -	3,670

Although the previous sewage contamination of all the above waters, with one exception, is greater than that of Thames water, yet it has much less significance, on account of the excessive amount of filtration which these waters have received in the oolite or chalk, and which may be presumed, with considerable probability, to have removed the noxious germs of organisms present in the excrementitious matters with which the waters had been in contact. The danger, therefore, attending the domestic use of water once contaminated with sewage or manure matter is here reduced to a minimum, and, with stringent precautions against the admixture of surface water, may, perhaps, be regarded as almost a vanishing quantity.

The great objection to these waters is their excessive hardness, which exceeds that of Thames and Lea water by about 6°. It is true that they may be softened to about one-fifth of their natural hardness by the application of Clark's process; but there appears to be no hope of this somewhat delicate chemical operation being carried out successfully upon such a vast volume of water as that supplied daily to the metropolis, when it is seen that the very simple mechanical process of filtration through sand is not efficiently performed in the case of the present water supply. After trying Clark's process for some time at Plumstead, the engineer to the Kent Water Company states that he was compelled to abandon it as utterly impracticable. The plan is still used at Caterham and Tring, but upon a scale far too small to permit of any safe conclusion being drawn as to its applicability to the entire supply of the metropolis.

Notwithstanding the small proportion of actual organic matter in the chalk waters of the London basin, they are still for domestic purposes much inferior to the Welsh and Cumberland samples, as is seen from the following comparison:—

* May 20th, 1868.
† Feb. 18th, 1868.

	Total solid impurity.	Organic carbon.	Organic nitrogen.	Previous sewage contamination.	Hardness.
Head Springs of Thames -	28·25	·014	·009	3,260	21·9
Amwell Well - - -	31·88	·076	·009	3,740	22·4
Otter Spring (Watford) -	32·36	·026	·012	3,920	24·7
Artesian Well at Caterham -	31·08	·020	·006	0	23·4
„ „ Croydon -	32·00	·040	·007	5,200	22·0
„ „ Deptford -	41·20	·053	·006	3,540	27·1
„ „ Bromley -	31·20	·033	·008	3,670	20·5
Bala Lake - - - -	2·79	·227	·001	0	·4
Ullswater Lake - - -	3·63	·067	·000	0	1·9
Thirlmere Lake - - -	2·66	·194	·004	0	·7
Haweswater Lake - -	3·56	·158	·004	0	1·3

The principal feeders of the Thames which we have examined, exclusive of the head waters, are, on the other hand, without exception, ill adapted, if not utterly unfit, for domestic purposes. They are all decidedly inferior to the Thames itself at Hampton. Near their source, the Kennet, the Wey, and the stream from Bagshot sands are clear, and the first-named stream is also colourless; but, with the exception of the Thame, they are all, where they join the Thames, turbid, and when viewed in a quart decanter, exhibit a yellowish, greenish-yellow, or brownish yellow colour. With the single exception of the stream from Bagshot sands, they all contain a large amount of highly nitrogenized organic matter, indicating sewage or manure pollution which has not been destroyed by oxidation. The small proportion of organic nitrogen to carbon in the stream from Bagshot sands shows the organic matter to be of vegetable origin, indeed the deep brownish yellow colour of this water proves that it contains peaty matter, and in such quantities as to render it unfit to be used as a beverage.

With the exception of the last-named stream, and the Kennet, just above Reading, all these affluents of the Thames exhibit a considerable previous sewage contamination, a charge against them which is not mitigated by excessive filtration, as in the case of the chalk and oolite waters already alluded to.

The hardness of these waters is greater than that of Thames water as delivered in London, with the exception of the water of the Mole, which is somewhat softer, that of the Wey above Godalming, and that of the stream from Bagshot sands, which are much softer, the last being in this respect fully equal to the average of the samples from Wales and Cumberland, which we have already reported upon.

It will be seen from the following comparison of the analytical results yielded by these feeders of the Thames with the mean of those given by Thames water as delivered in May last, by the five companies supplying the metropolis from that river, that not one of these affluents could be substituted with advantage for any portion of the present metropolitan supply. The River Mole alone exhibits in some respects slight advantages over Thames water; but these are more than counterbalanced by the notorious turbidity of this river, and the great difficulty of rendering its waters clear by filtration.

	Total solid impurity.	Organic carbon.	Organic nitrogen.	Proportion of organic nitrogen to organic carbon, N : C =	Previous sewage contamination.	Hardness.
Thames water as delivered in London, May 8th 1868*	26·40	·184	·023	1 : 8·0	1,275	18·6

* Weekly return of Registrar General, No. 22, 1868.

II. *The Change in the Chemical Character of Thames Water during its flow through a populous District.*

The alterations in the chemical character of Thames water during its flow from the oolitic head springs to Hampton are shown in the following table, in which the samples are arranged in the order of the places whence they were taken, from the sources of the river downwards. I have also added the average of the results obtained in the analysis of the waters supplied to London on the 8th of May last by the West Middlesex, Grand Junction, and Southwark Com-

panies, who abstract water from the Thames at Hampton, and by the Chelsea and Lambeth Companies, who draw from the Thames below the junction of the Mole. These additional results are extracted from my Report to the Registrar General, contained in his weekly return, No. 22, 1868.

Places where samples were taken.	Total solid impurity in 100,000 parts.	Organic carbon.	Organic nitrogen.	Proportion of organic nitrogen to organic carbon.	Nitrogen as nitrates and nitrites.	Ammonia.	Total combined nitrogen.	Previous sewage contamination.	Hardness before boiling.	Hardness after boiling.	Date of collection of sample.	Distance of place of collection from sources of Thames.	Population on banks of river and tributaries between places of collection. (Census 1861.)*

* I have much pleasure in acknowledging the valuable assistance of the Secretary to the Rivers Commission, S. J. Smith, Esq., in the laborious compilation of this population table.

It is obvious, from an inspection of the foregoing table, that such a series of analyses, although otherwise highly instructive, can only very imperfectly illustrate the chemical changes which *a given volume of water* undergoes, during its flow from its source to Hampton. In the first place, the number of samples of tributaries examined, though considerable, is far too small to enable us to judge of the total effect, upon the main body of the stream, which is produced by its affluents. Thus, of the head waters of the river which, meeting at or near Lechlade, form the main stream of the Thames, the springs constituting the sources of the Thames proper, the Churn, and the Coln, only were examined; whilst the waters of the Swillbrook, the Leach, the Ray, and the Cole, were left unexplored, although the two last are very considerable streams. Again, of the great number of tributaries below Lechlade, only seven were examined, and even in these cases, where the quality of the affluent was ascertained, its relative quantity was not determined. It is also well known that the Thames is fed by numerous powerful springs, which rise in the bed of the stream at various points of its course.*

Secondly, the samples could not possibly be collected at the times when the same body of water was passing the different points where they were obtained; in fact, the same body of water flowing in a river does not pass consecutively any series of points on the banks; because the superior water strata flow more rapidly than the inferior, and the centre of the stream than the lateral portions, consequently, even if a float had been placed in the stream, and each sample taken at the moment when the float passed the place of collection, the consecutive samples would still have been very far from representing one and the same volume of water moving down the bed of the river. It is indeed evident that the Thames, in its flow from its source to Hampton, is constantly undergoing changes, now tending to purification, now to pollution; here it receives a tributary purer than itself, there one more polluted; at one place it is pent up by a weir, and flows sluggishly over a thick stratum of putrescent mud; then it dashes down the weir and flows as a rippling stream over a clean pebbly bed, becoming aerated to the maximum; now it receives the sewage of a town, and then it is reinvigorated by a gush of spring water in its bed; and these complicated changes are not merely affecting successive individual volumes of water as they flow on, but these volumes immediately afterwards lose their individuality, owing to the varying velocity of flow in different parts of the same river section. No series of analyses, therefore, however great the number of samples, or care bestowed on their collection, could, in the case of such a river as the Thames, illustrate exactly the changes produced in a stream by any one of the numerous causes of change above enumerated—the effect of the population residing on the banks, for instance.

Nevertheless, the above series of analyses demonstrates conclusively certain points of the highest importance, as regards the use, present and prospective, of the Thames, or its tributaries, for the supply of the metropolis with water.

* See the evidence of the Rev. J. C. Clutterbuck, in the Report of the Select Committee on the Thames River, 1865, page 53.

The head waters of the Thames which we have examined, containing but a very small proportion of organic impurity, become by the time they reach Lechlade, as impure, in this respect, as the Thames at Hampton; the organic carbon is increased nearly tenfold, and the organic nitrogen nearly fourfold. On the other hand, the previous sewage contamination, which, as indicated by analysis, is always to be regarded as the minimum, has decreased from 3,260 to 1,270; this may be due to the comparative freedom from such contamination of the important feeders of the Thames above Lechlade which have not been submitted to analysis; or it may arise from the action of aquatic vegetation upon the head waters during their average flow of 21 miles to Lechlade; the latter is certainly one of the causes, and it is probably the more important of the two. It nearly ceases in winter.

Judging from the samples taken, the Thames at Hampton contains less solid impurity and organic nitrogen than at any other point of its course; the organic matter is also less highly nitrogenized here than at any point higher up the stream, except at the foot of the Weir above Staines, where, however, the difference in favour of the latter point is very slight; the proportion of nitrogen to carbon being 1 : 11·2 at Staines, and 1 : 10·8 at Hampton. After leaving its sources, therefore, the water of the Thames is purer and better adapted for domestic purposes at Hampton than at any other point in its course. This highly remarkable circumstance, coupled with the fact that between Staines and Hampton, a distance of only 12½ miles, the Thames water suffers a diminution of 3·33 parts of solid impurity, ·044 part of organic carbon, and ·003 part of organic nitrogen in 100,000 parts of water, indicates some powerful cause of amelioration between these points. A reference to the ordnance map shows that two very important tributaries, the Colne and the Wey, enter the river between the points at which the Staines and Hampton samples were taken. No sample was collected from the River Colne, and the analysis of the sample of the Wey above Godalming only partially accounts for the amelioration; since although it contained 16·37 parts of solid impurity per 100,000 less than the Thames at Staines, it yielded ·234 part more organic carbon, and ·038 part more organic nitrogen. It is to be remarked, however, that the Wey sample was collected on April 21st, when Mr. Pole says, "river somewhat in flood and rather turbid," whilst the Staines and Hampton samples were taken on the 2nd and 4th of May respectively. It is to be regretted that samples of these affluents were not taken near their junction with the Thames, on the same day that the Staines and Hampton samples were collected. With the evidence now available, it is impossible to do more than conjecture the cause of the remarkable amelioration of the Thames between Staines and Hampton.

With a view to ascertain the effect of the towns of Oxford, Reading, and Windsor, upon the quality of the river water, three samples were taken in each case, viz., one immediately above the town, another at a point below the town where the drainage becomes mixed with the water, and a third at a point some miles below, but before the river receives any further affluent, or is influenced by any other important riparian source of alteration; the object of this latter sample

being to ascertain what change was produced on the quality by the flow. At Oxford and Reading, where a tributary entered through the town, it was also necessary to take a sample of the tributary above the town.

At Oxford the effect of the sewage upon the filtered waters of the Thames and Cherwell is not very striking; it is, in fact, to some extent concealed by the material difference in composition of the Thames and Cherwell as they enter Oxford, and by the circumstance, that the relative volumes of these streams are unknown. The Cherwell is, in nearly every respect, more impure than the Thames, as might be expected from its having been contaminated by the sewage of Banbury (pop. 11,000) and other places. The united waters, after receiving the pollutions of Oxford, contain, in 100,000 parts, only ·015 more combined nitrogen than the Cherwell; but if we assume the volume of the Cherwell to be one-fourth that of the Isis, then the following table shows the composition of the mixed waters before and after admixture with the Oxford sewage.

——	Before admixture.	After admixture.	Addition to impurity by admixture.
Total solid impurity -	29·3	31·6	2·3
Organic carbon - -	·212	·216	·004
„ nitrogen -	·027	·028	·001
Total combined nitrogen -	·256	·305	·049
Previous sewage contamination.	1962	2450	488
Hardness - - -	19·1	19·1	0

The rate of flow of the combined streams of the Isis and Cherwell below Oxford is unknown, but assuming it to be 200,000,000 of gallons in 24 hours, the addition to the total combined nitrogen in the filtered river water ought to be about ·041. The above table gives it ·049 in 100,000 parts.

The change produced in the quality of the water by the flow of the river down to the lock above Abingdon (about seven miles), ought to be shown by a comparison of the sample taken below Oxford with that collected just above Abingdon, but unfortunately the latter sample was not taken on the same day as the former, and therefore the results of the two analyses are not comparable quantities; indeed, the increase in hardness of no less than 2·9 degrees at Abingdon shows that from some cause, independent of the mere flow of the stream, the character of the water had materially altered during the time which elapsed between the taking of the two samples. The water at the lock above Abingdon contained, after filtration, exactly the same amount of solid impurity as that below Oxford. It also contained ·018 part per 100,000 more organic carbon, ·002 part less organic nitrogen, ·002 part more ammonia, ·032 part of combined nitrogen, and 300 parts of previous sewage contamination less than the water below Oxford.

At Reading, a similar series of samples was taken, but here, as at Oxford, a large tributary, of unknown proportional volume and of very different chemical character, enters the Thames, and complicates the result. Reading is only partially sewered, but from the evidence given before the Rivers Pollution Commission, a large amount of sewage finds its way into the Kennet, and night-carts are also emptied into the stream. Mr. Pole states that the samples around Reading were collected after a few days of showery weather, the Kennet "near its junction with the Thames "running, at a rough estimate, about 200 millions of gal-"lons per day." The volume of the stream could, therefore, not be much smaller than that of the Thames itself. Assuming it to be two-thirds that of the Thames just above the junction, the following table exhibits the composition of the united filtered waters before and after admixture with the Reading sewage:—

——	Before admixture.	After admixture.	Addition to impurity by admixture.
Total solid impurity -	29·87	28·6	0
Organic carbon - -	·266	·300	·034
„ nitrogen -	·035	·049	·014
Total combined nitrogen	·219	·198	0
Previous sewage contamination - -	1520	1170	0
Hardness - -	20·4	18·2	0

These results show that in passing Reading the waters of the Thames and Kennet receive a well-marked accession to the organic matter which they previously contained; but the analytical numbers also indicate that the waters of the two streams had not become uniformly mingled at the point where the sample of the mixed waters was taken, which was only a quarter of a mile below the junction of the two streams. If we assume that at the point where the sample was taken the waters were mixed inversely as the proportions above given, then the accession of "total solid impurity," "total combined nitrogen," and "previous sewage contamination," in the above table, would receive positive values.

The last sample of the Reading series was taken at Shiplake Mill, about five miles below Reading, on the day following that on which the other samples of the series were collected; no safe conclusions can therefore be drawn from the results of its analysis, regarding the effect of the flow of five miles upon the quality of the water contaminated with the Reading sewage. A comparison of the impurities in the filtered water, taken just below the town, with those in the filtered sample collected at Shiplake Mill, shows an increase of 1·4 part of total solid impurity in 100,000 parts of water, of 670 parts of previous sewage contamination, and of 1·8 of hardness; whilst it shows a decrease of ·037 part of organic carbon, and ·017 part of organic nitrogen.

The last series of samples was taken at Windsor, viz., one about half a mile above the bridge; a second at the ferry at Old Windsor, nearly two miles below the sewer outfall; and a third at the foot of the weir above Staines, just before the junction of the Colne. As no considerable tributary enters the Thames between the points at which these samples were collected, and as they were also all taken on the same day, the chief disturbing causes which affected the two other series were here absent. The following table exhibits a comparison of the analytical results yielded by the three filtered samples:—

——	Above Windsor.	Two miles below sewer outfall.	Increase of impurity after admixture with sewage.	Five miles below sewer outfall.	Decrease of impurity after flow of three miles.
Total solid impurity in 100,000 parts	31·0	30·4	0	31·2	0
Organic carbon - -	·259	·289	·030	·304	0
„ nitrogen -	·028	·029	·001	·027	·002
Total combined nitrogen - - -	·235	·243	·008	·242	·001
Previous sewage contamination - -	1750	1820	70	1830	0
Hardness - -	22·2	22·4	·2	20·8	1·6

An inspection of this table would indicate that the sewage of Windsor produces practically no effect upon filtered Thames water, and further that a flow of three miles effects substantially no alteration in the proportion of the several impurities; but it would be hazardous to draw either of these conclusions from this single series of analyses. The towns of Eton, Clewer, Windsor, and Datchet contain, according to the census returns of 1861, a population of 18,198. Supposing the whole of this population to drain into the Thames, and the volume of the river as it flows past Windsor to be 500,000,000 gallons daily, the proportion of organic nitrogen in solution contributed to the stream would amount to only ·002 part in 100,000 parts of water, the above analyses show ·001, the increase of previous sewage contamination ought to be 100, analysis shows 70, and the theoretical increase of total combined nitrogen is ·010, whilst the accession actually found amounts to ·008. These numbers are, however, so small that they might well be regarded as falling within the limits of experimental error; they certainly cannot be taken as a basis for the solution of either of the questions proposed.

The effect of flow upon the nitrogenous organic matters dissolved in Thames water can be more certainly investigated, by taking as a basis, the contamination produced upon the 100,000,000 gallons of water flowing, according to Mr. Pole's estimate, past Lechlade, by the 58,015 persons residing on the banks of the tributaries above that point. This contamination, as shown by analysis, amounts to ·133 part organic carbon and ·033 part organic nitrogen in 100,000 parts of water. Taking this as the relation between riparian population and river contamination, it follows that the 834,248 persons residing on the banks of the Thames and its tributaries above Hampton ought to communicate to 800,000,000 gallons of water, the average daily flow of the river past Hampton, a contamination equal to ·239 part of organic carbon and ·059 part of organic nitrogen in 100,000 parts of water.

The amounts actually found at Hampton by analysis were ·260 part of organic carbon and ·024 part of organic nitrogen in 100,000 parts of water, thus showing an excess of ·021 part of organic carbon and a deficiency of ·035 part of organic nitrogen, the first ascribable to the accession of

peaty and other similar vegetable matters, and the last to oxidation or precipitation of a portion of sewage matter during the flow of the river from Lechlade to Hampton. By calculation from the average amount of soluble organic nitrogen in sewage, the drainage of 834,248 persons into the Thames ought to communicate to the river at Hampton ·062 part of organic nitrogen in 100,000 parts of water—a number which nearly agrees with that (·059) deduced above from, first, the analysis of Thames water just below Lechlade, and, second, the population above the point at which the sample analysed was taken.

III. *The Extent to which Town Sewage can be purified by its Passage over or through Land in the Process of Irrigation.*

Towards the solution of this problem the series of analyses given at page 3 were made. This series illustrates the composition of the water supplied to Croydon, the change which it undergoes in being converted into sewage, the composition of this sewage after it has been used for irrigation, the composition of the River Wandle after admixture with the purified sewage, and, lastly, the composition of the same river after a further flow of one mile. The following table shows the alteration in the composition of the Croydon water in its passage through the successive stages just mentioned. All the numbers refer to 100,000 parts of the water or sewage:—

	Excess of impurity after conversion into sewage.	Excess of impurity after irrigation.	Excess of impurity after mixture with the Wandle.	Excess of impurity after flow of one mile in the Wandle.
Total solid impurity.	11·6	2·4	0	0
Organic carbon -	2·758	·059	·060	·059
„ nitrogen -	1·149	·030	·024	·017
Ammonia -	2·190	·001	·000	·000
Total combined nitrogen.	2·401	0	0	0
Hardness -	1·4	1·4	0	0

An inspection of this table and the one at page 3 shows that the Croydon sewage is very weak. According to Hofmann, Witt, and Way, average London sewage contains of combined nitrogen about 10 parts in 100,000, consequently the Croydon sewage is scarcely one-third of the strength of average London sewage; in fact it is known that the Croydon sewage becomes mixed with a large volume of subsoil water before it reaches the irrigated land at Beddington; nevertheless the great amount of purification effected by this application of the sewage to the land is highly remarkable, and if supported by repeated analyses would prove that for the conversion of the sewage of towns into water as pure as that usually met with in rivers flowing through cultivated land, nothing more is necessary than to apply it to a surface of land of about 10 acres to each 2,000 of the population contributing the sewage.

Unfortunately, however, the amount of purification exhibited by the above series of analyses must be regarded as exceptional, for, although all experiments hitherto made show that sewage may be ameliorated by being employed for irrigation to an extent which cannot be approached by any practical chemical means hitherto devised, yet no analytical determinations, with which I am acquainted, exhibit a degree of purification at all so great as that observed in the results just given. The effluent water from the Beddington meadows at Croydon has been repeatedly examined both by Dr. Odling and myself in summer and winter, but the amount of purification observed previously to the above, by either of us, still leaves the following excess of impurity in the effluent water compared with that present in the water supplied to Croydon:—

	Excess of impurity after irrigation.		
	Maximum.	Minimum.	Mean.
Total solid impurity - -	5·40	2·10	3·75
Organic carbon - - -	·716	·627	·671
„ nitrogen - -	·199	·185	·192
Total combined nitrogen -	·361	0	·218

The above numbers all relate to 100,000 parts of water.

Conclusions.

The conclusions arrived at from the foregoing investigation of the waters of the Thames basin may be thus summarised:—

1. The head waters of the Thames and the waters from chalk wells and springs in the Thames valley contain but a very small proportion of organic matter, which is, however, highly nitrogenised. They are very hard, and, with one exception (the Caterham well water), exhibit a high previous sewage contamination. Although markedly superior to the river waters at present supplied for domestic purposes to the metropolis, they are much inferior to the Welsh and Cumberland samples.

2. All the feeders of the Thames (exclusive of the head waters) which have been examined, are, without exception, ill adapted if not utterly unfit for domestic purposes. They are all decidedly inferior to the Thames itself at Hampton, and consequently none of them could be substituted with advantage for any portion of the present metropolitan supply.

3. The head waters of the Thames are polluted by sewage or manure matters soon after leaving their sources, and on reaching Lechlade are contaminated even to a greater extent than the Thames water delivered in London.

4. The precise effect of the flow of a stream, in purifying the water from sewage or manure matters, cannot be clearly ascertained from the foregoing investigation; but the analytical results demonstrate that at no part of its course does the Thames become freed from the soluble animal organic matters with which it is contaminated, although the total amount of these matters becomes diminished as the stream pursues its course.

5. After leaving its head springs, the water of the Thames is purer and better adapted for domestic purposes at Hampton than at any other point in its course.

6. Irrigation, properly carried out, purifies sewage to a great extent, but not sufficiently to render it admissible into potable water without danger; the risk arising not only from the considerable amount of animal organic matters which the effluent water still retains in solution, but also from the absence of any guarantee for the removal of the germs or other noxious suspended matters which are frequently present in sewage.

E. Frankland.

Note by Dr. Odling.

It may assist the Commission, in interpreting the results of our analyses, to have their attention drawn to the following points:—

1. That unoxidized nitrogen, or nitrogen in the forms of organic substance and ammonia, is the characteristic constituent of animal excretions; and that if the entire daily excretions of the 800,000 persons living above the Thames at Hampton were added at once to 800,000,000 gallons of water, or the daily quantity of water flowing past Hampton (*i.e.*, if the excretions of one average person were added to 1,000 gallons of water), they would give to the filtered water a proportion of unoxidized nitrogen amounting to ·3 part in 100,000 parts.

2. That whereas, in fresh animal excretions almost the whole of the nitrogen exists in the form of organic substance, and but a minute proportion in the form of ammonia, in ordinary town sewage about four-fifths of the dissolved nitrogen has become changed into ammonia, only one-fifth remaining in the form of organic substance; so that if the sewage of 800,000 persons were included at once in 800,000,000 gallons of water, it would give to the filtered water a proportion of nitrogen in the form of ammonia amounting to ·24 part, and a proportion of nitrogen in the form of organic substance amounting to ·06 part in 100,000 parts.

3. That, according to the tables of results, the excess of unoxidized nitrogen in Thames water at Hampton, above that in the Head Springs water, is ·015 part, and the entire amount of unoxidised nitrogen in the water at Hampton, but ·024 part in 100,000, the two waters being alike free from ammonia; whilst, of feeders, &c., of the Thames draining sparsely populated districts, the quantity of unoxidised nitrogen amounts in the Kennet above Hungerford, to ·034 part, including ·003 of ammonia; in the Thames below Lechlade, to ·056 part, including ·003 of ammonia; in the stream from Bagshot sands, to ·046 part, including ·003 of ammonia; in the Wey above Godalming, to ·066 part, including ·001 of ammonia; and in the Thame, to ·073 part, including ·001 of ammonia, in 100,000 parts of water.

William Odling.

APPENDIX AY.

Dr. Pole's Report on the Collection of Further Samples of Water from the Thames Basin.

Committee Room F., House of Lords,
Dear Sirs, Westminster, S.W., Oct. 29, 1868.

In compliance with the desire expressed in Dr. Frankland's letter to me of the 8th inst., and which was assented to by his Grace the Duke of Richmond on behalf of the Commission, I have collected and forwarded to Dr. Frankland the four additional samples of water mentioned by him.

They were all taken, in the same manner as the former samples, on the 28th of October. There had been moderate rain some days before, but three fine days had intervened before the collection, and, as far as I could learn from persons in the neighbourhood, all the rivers were in their usual average condition, both as to quantity and quality.

The following is a list of the samples forwarded:—

From the Thames, just below Staines Weir and above the junction of the Colne (11·20 a.m.):—

Four gallons. Bottles Nos. 36 and 51.
Temperature 8½° Cent.

From the main stream of the Colne, about 200 yards above its junction with the Thames (noon):—

Four gallons. Bottles Nos. 60 and 83.
Temperature 8°.

From the Wey, about 200 yards below the entrance into it of the Basingstoke Canal, and about half a mile above its junction with the Thames (2·45 p.m.):—

Four gallons. Bottles Nos. 35 and 67.
Temperature 8½°.

From the Thames, just above the intake of the Water Companies at Hampton (3·45 p.m.):—

Four gallons. Bottles Nos. 34 and 96.
Temperature 9°.

I am, dear Sirs, yours faithfully,
Wm. Pole.

To Dr. Frankland, F.R.S., and Dr. Odling, F.R.S.

APPENDIX BB.

Report on Gravitation Water Supplies to Large Towns.

To the Chairmen of the London Water Companies.

Gentlemen,

Having been instructed by you to investigate the general question of gravitation supplies of water to large towns, I visited Manchester, Liverpool, Glasgow, Newcastle, and other places, and procured information which has enabled me to arrive at the results given in the following report.

Manchester.

The present population of Manchester is about 470,000, and the quantity of water supplied is about 15 millions of gallons per day, or nearly 32 gallons per head per day for all purposes.

The yield of the spring water in the upper valley of the river Etherow, which forms the gathering ground for the water supply, is stated to be 16 cubic feet per second, or 8½ millions of gallons per day; the balance of 6½ millions being supplied out of the storage reservoirs.

The compensation water to the mills is now 55 cubic feet per second for 12 hours per day, or nearly 15 millions of gallons per day; thus making the present demand upon the works equal to about 30 millions of gallons per day.

To supply this quantity from the drainage ground of 18,900 acres will require 25½ inches rainfall to run off the ground and be stored.

The average rainfall of the last 14 years, over the water-shed, has been about 46 inches. From similar districts the available *minimum* quantity has fallen to less than half the average rainfall; it would therefore seem that until the extra storage reservoirs, now in course of construction, are finished, the safe limit of this gravitation supply—that is, the *available minimum*—has been nearly reached.

From information gathered on the spot, I ascertained that fears were entertained of the water running short in 1865. It appears, however, that the two largest store reservoirs, viz., Woodhead and Torside, have practically never been filled within 15 to 20 feet of their full height; in the case of Woodhead, because it was thought unsafe to fill it owing to a landslip, and to the unsoundness of the embankment; and in the case of Torside, because as a matter of prudence it was thought desirable to keep down the full head, and only increase the level year by year a foot or two; besides which the filling to high-water mark would have drowned out the Crowden Bleach Works, situated near the head of this reservoir. These bleach works have been purchased and are now in course of removal.

Since the year 1865, two new compensation reservoirs have been in course of construction in the valley below Rhodes Wood reservoir, called the Valehouse and Bottom's reservoirs, which are intended to hold 750 million gallons, or 50 days' supply of compensation water; and on their completion it is intended to empty the Woodhead reservoir, and construct a new embankment and other works, to admit of its being filled with safety.

These several additional stores of water will increase the capacity of the works and enable them to supply all demands for probably some years to come; but, at the same time, they are evidence of the weakness of the supply in times of *extreme drought*.

Since the works were constructed, the compensation water given out of the reservoirs to mills and works has been decreased from 75 to 55 cubic feet per second for 12 hours per working day, thus affording an increase of 5,400,000 gallons of water per day for the use of the town. I understand this water has been acquired by purchase from the mill owners, and serves as an additional indication of the weakness of the supply; and but for this relief from the original impost, the works would probably have failed to provide a full supply of water in 1865.

Manchester is most favourably situated for a gravitation waterworks; the abundance of rainfall, and the proximity of high lands with rapid water-sheds, render it a favourable example of a *gravitation* supply, yet there can be little doubt that the spread of population will absorb the increased quantity from the works now constructing, and then the occurrence of three or four dry years in succession will again test its powers of endurance, and new supplies will have to be sought for in more distant localities.

Liverpool.

The present population is about 620,000, and the quantity of water supplied is about 17 million gallons per day, or 27½ gallons per head per day for all purposes. Of this quantity about 7½ millions per day are obtained from wells sunk into the red sandstone, and the remainder, or 9½ millions, from the Rivington Gravitation Works.

The compensation water stipulated to be given to the mills from the Rivington works is 8,300,000 gallons per day, and after deducting this quantity, the total yield of these works in the best years has never exceeded 17 millions of gallons per day; while the maximum quantity supplied to Liverpool in any year has not much exceeded 11 millions of gallons per day, owing to the water run to waste from time to time for want of sufficient storage. Moreover, the quantity of water supplied on the average of the last 11 years has only been a trifle in excess of 9,000,000 gallons per day, while in the years 1864, 1865, and 1866, the average was under 8,000,000, and in 1865 alone only 6,177,000 gallons per day.

The late Mr. Robert Stephenson, in his report of 1850, after fully investigating this subject, stated "that an uniform "supply of 12 or 13 million gallons per day may, in my "judgment, be reckoned upon with absolute certainty."

The average rainfall of the district was originally taken at 48 inches, of which 36 inches was assumed to be available, and one-third of this, or 12 inches, was allowed for mill compensations, leaving 24 inches for Liverpool.

The actual rainfall for an average of 17 years has been 45·70 inches only; the average of 11 years' rainfall delivered to Liverpool has been only 14½ inches, and in 1865 only 9¾ inches, instead of the 24 inches depth originally anticipcted.

The reservoir capacity, compared with the area of the gathering ground, is 50,000 cubic feet per acre, which is a very large amount, notwithstanding which a new store reservoir is in course of construction, 80 acres in area, and intended to hold 1,200 millions of gallons of water. With this additional capacity the entire storage will amount to 68,500 cubic feet per acre, which in a run of dry years has little chance of being filled; indeed, the corporation engineer estimates that even with this increase the average yield will only be equal to 10½ million gallons per day, while reliance should not, he says, be placed on more than 9 million gallons per day in cycles of three dry years.

It thus appears that the ultimate value of this gravitation supply is practically reached, for even if the new store reservoir above alluded to had been originally constructed, and the mean yield of the first five years, viz., about 12½ million gallons per day abstracted, it has been calculated by the engineer that in 1866 the whole of the supply would have been exhausted.

The pumping works for getting water from the red sandstone have been increased during the last two years so as to supplement the Rivington supplies, but this source is limited, as the water in the sandstone basin is gradually lowering, and it is evident that some larger and more comprehensive water supply must before long be brought to bear on Liverpool.

The corporation engineer has reported on various schemes for obtaining supplies more or less distant, and has recommended the Bala Lake scheme in Wales, distant from Liverpool about 45 miles in a direct line.

The Rivington Works are practically a failure as gravitation works; three dry years in succession reduce the available water to 6 millions of gallons per day, and four successive years of drought, which may very probably occur in future, would reduce it still further; and unless enormous reservoirs or lakes could be made, capable of storing the surplus waters of three or four years, these works must prove insufficient.

Penrith.

The particulars of the Penrith water supply (though not gravitation works) serve to show the excessive fluctuation in the quantities of water flowing from the Lake districts.

The town is supplied with water pumped out of the river Eamont, which is the only outlet from Ulleswater Lake. The works are about a mile distant from the town, and all the water required for it was in the first instance raised by the water power of the river; but in the year 1862 the river ran so low that there was scarcely enough water left to turn the wheel, and temporary steam power had to be resorted to to raise the water for the town. Since that year a permanent steam engine of 14-horse power has been fixed for use in short water seasons.

There is a flour mill near the waterworks wheel, which by arrangement has a right to half the water power.

From data obtained I find that in 1862 the quantity of water flowing from Ulleswater, with its gathering ground of about 54,500 acres, was reduced to 20 million gallons per day for some months.

The flow down the river on the 26th ultimo was 120 millions of gallons per day, being about the average flow; showing that in dry seasons the water is reduced to one-sixth the ordinary volume.

Glasgow.

The population of Glasgow is now estimated at about 500,000. The average quantity of water supplied during 1867 was 26½ million gallons per day, or about 50 gallons per head per day for all purposes. Of this water 22½ millions of gallons was supplied from Loch Katrine, and 3¾ millions from the Gorbals Gravitation Works.

Loch Katrine can be drawn upon to the extent of 7 feet of its depth, in which it contains a store of 650 millions of cubic feet, and the drainage ground to the lake being 23,300 acres, there are 28,000 cubic feet of storage capacity per acre.

The scheme was projected by Mr. Bateman as capable of supplying 50 millions of gallons per day to Glasgow.

The tunnels and works near the lake have been constructed of sufficient size to convey this quantity, but a 4-feet aqueduct pipe only has been laid through the valleys towards Glasgow for conveying 20 million gallons of water per day, the original intention being, as I am informed, to have another such pipe, and one of 3 feet, which would altogether convey the 50 million gallons.

Instead, however, of now laying down the second 4-feet pipe, the corporation are laying the 3-feet pipe, which will only increase the present quantity brought to Glasgow by 10 millions—that is to a total of 30 millions of gallons per day. At the same time they are now constructing pumping works on the river Clyde, some distance above Glasgow, to supply 7½ millions of gallons per day for manufacturing purposes.

I was informed by the corporation engineer that the reason for constructing these pumping works is as follows:—There has been for many years a weir across the Clyde, nearly opposite the eastern end of Glasgow Green and originally above the town, but, by the spread of population eastward, it is now nearly in the centre of that part of the river bordered by buildings. The weir was constructed by the old Glasgow Waterworks Company to form a reservoir of water to pump from during the low water of the tide. The manufactories on the river at present draw from this pond, but, on account of the quantity of sewage now flowing into the river, the commissioners are about to remove the weir higher up, and so let the tide at Glasgow ebb fully out. This will deprive the manufactories of their present pumping reservoir, and therefore the corporation are making the works in question to supply them with water.

Considering that one foot additional diameter to the new pipe now being laid from Loch Katrine (viz. increasing it from 3 to 4 feet) would convey an additional 10 million gallons per day, the construction of the pumping works seems to indicate a mistrust in the Loch Katrine supplies during dry years, as it would certainly be cheaper to increase the size of the main and bring in 10 million gallons of water by gravitation than erect pumping works to supply inferior water, in less quantity, at continual cost.

That the Loch Katrine Works can supply 50 million gallons of water to Glasgow in years of extreme drought seems very doubtful. In Mr. Bateman's report of 1853, he states, upon this subject, "Observations upon the volume "of the river Teith flowing over Deanston Mill dam have "been kept for many years. The driest year and the year "in which the longest drought occurred during the period "of the observations, was the year 1826. In that year there "was no rain from the middle of April to the beginning of "August, and the water of the river was insufficient to "drive the machinery at full work, from 6th of May to the "15th August, a period of 100 days."

The quantity of water measured during this time as flowing off the entire drainage area of 122,200 acres to Deanston, was 3,820 cubic feet per minute; and the quantity due to Loch Katrine district was, as apportioned by Mr. Bateman, 1,700 cubic feet per minute. This gives 37 cubic feet per minute per 1,000 acres, and applying this to Loch Katrine alone we get 864 cubic feet per minute, or 1¼ million cubic feet per day as the entire yield of the district. Then, supposing the store of 650 million cubic feet in the lake to have been full at the beginning of this period, and adding the yield as above, the quantity that could have been supplied was 48 million gallons per day for 100 days. But as it is very unlikely in such a year that the store would be full at the commencement of the dry period, or that the full supply could have been given from the natural streams without storage immediately after the 100 days had passed, there seems no doubt that the full supply from these works would have failed that year.

Mr. Bateman, in his own calculations for that year, gives, as the total yield of the Loch Katrine *district* (which includes Loch Venachar), for that period 71,500,000 gallons per day, and if the original proposals had been carried out to give half this to the mills on the river Teith, he admits the quantity left for Glasgow would have been only 35¾ million gallons per day. So that, even if the 48 millions could have been supplied for 100 days of that year, it must have been at the sacrifice of the compensation water sent down the Teith, which would have been only 23 or 24 instead of 40 millions of gallons per day as now stipulated.

I conclude from these data that the Loch Katrine Works in seasons of excessive drought, and with their present storage, may be reduced to less than 30 million of gallons per day, if the full compensation to the Teith is to be continued.

Newcastle-on-Tyne.

The population of Newcastle is now about 200,000, and the quantity of water supplied 5½ millions of gallons per day, or 27½ gallons per head per day.

The original gravitation works constructed in 1846-7-8, at Whittle Dean, were designed for the supply of about 3¼ million gallons per day. The storage capacities of the reservoirs being 215 million of gallons, and the gather 4,340 acres. The storage was therefore equal to 7,900 cubic feet per acre only.

The quantity of water used in the town at the commencement of the works was about 1½ million gallons per day, so that the reservoirs contained 143 days' supply of that quantity, or 66 days' of the full quantity of 3¼ millions per day.

The water was introduced in 1848, and in 1850 the supply failed, and the old pumping establishment from the river Tyne had to be resorted to. Since that period additional storage reservoirs have from time to time been constructed, which have also in dry years failed to provide the necessary supply of water. The latest large store reservoir added to the works was finished and filled in the spring of 1857, and the storage was then 500 millions of gallons, or ninety days' supply of the present quantity. The rainfall of that year in the Whittle Dean district was only 22 inches, and a drought of eight months' duration commenced with the month of December and continued up to the May of 1858, only 3 inches of rain falling during the time. The consequence was, even the increased store was exhausted early in 1857, and was not replenished during that winter; and in 1858 Newcastle had to be supplied from the old pumping works from the river Tyne, which were of necessity again had recourse to.

The present available storage room is still only 500 million gallons, but the gathering ground was increased about the year 1860 to 17,300 acres, which gives a storage capacity of only 4,900 cubic feet per acre, or less than that originally designed.

The quantity of water expected to be obtained has not been realized in dry years. The average rainfall of the district was assumed to be 24 inches, and of this quantity it was expected 12 inches would be available. The rainfall has proved on the *average* of the last 18 years to be 24 inches as taken originally, but the realized quantity of water has in years of drought been little more than 6 inches, or one-fourth only of the average, and half the anticipated quantity.

Feeling that this critical position is unsafe, the company are now erecting permanent pumping works, to pump water from the river Tyne at Newburn, to the extent of 5 million gallons per day.

Bristol.

Bristol was supplied by gravitation works completed in 1851, for bringing water from the Mendip Hills and other springs in Somersetshire. The full quantity proposed to be supplied was 4 million gallons per day. That this quantity could not be realized in cycles of dry years became apparent in 1860, and measures were taken to supplement the supply by pumping from wells on the line of works.

In 1862 the company obtained an Act of Parliament enabling them to construct additional storage reservoirs, but before these could be completed, the rain deficiency in the winters of 1861, 1862, and 1863 had so seriously affected the springs, that it became evident early in 1864 there would be a dearth of water, and recourse was, in that year, had to all the springs and available sources round Bristol, which were temporarily pumped to supplement the gravitation supplies. Notwithstanding these efforts, the city was limited to six hours per day supply for some time; the store of water was exhausted, and the springs did not yield more than 350,000 gallons per day.

The result of this experience has been the carrying out of a pumping project for obtaining a permanent supplementary supply of water from springs about eight miles from Bristol.

These works are completed and will be resorted to on the approach of dry seasons.

The additional store reservoir has also been completed, and the total storage for Bristol (apart from the compensation storage for mills) is 350 million gallons, or 88 days' supply of 4 million gallons per day.

General Conclusions.

The general conclusions to be drawn from the data I have given in the preceding pages respecting the largest gravitation water supplies in this country, are as follows:—

That none of the works alluded to have completely fulfilled the anticipated results.

Manchester and Glasgow are favourable examples of gravitation works, but exhibit signs of deficiency when tested for cycles of dry years; and of the *five* large towns alluded to, *four* have already erected or are erecting, pumping works in aid of the gravitation supplies.

There is not yet sufficient experience of the variations of rainfalls to arrive at any fixed data for guidance as to the probable minimum quantities in cycles of years; for instance, taking the recorded rain at Greenwich from 1817 to 1867, there is only one example of five successive years which were all below the average fall, viz. 1854 to 1858 inclusive, in which only 100 inches of rain fell. The average fall for the 51 years being 25¼ inches, there was actually a deficiency of 26 inches of rain in these five years, or one whole year's rain. This having occurred only once in 51 years, proves that much longer experience is required to know the various fluctuations that may occur.

In the case of the Glasgow Works, the Deanston observations on the river Teith showed that in the year 1826 the river was lower than at any other period during the observations. I do not know how long before that year the observations extended, but assuming them as commencing in 1825, this case gives only one year in a cycle of 40 or more years as an extreme example.

Again, in the Newcastle case there has since 1848, or during 20 years, been but one example of extreme drought, viz. that of 1857-8, in which only 3 inches of rain fell in eight months.

Other cases could be cited, but these are sufficient to show that the possible variations of rainfall in cycles of years are not yet sufficiently known to fix the absolute minimum quantities of rain for any given district. What has occurred only once in 50 years may occur to a still greater extent during the next 50 years; and when it is considered that these periods of drought are the only real guides as to the efficiency of gravitation waterworks, it is evident that past experience has been insufficient, and that failures have in consequence occurred.

There is also a deficiency of experience with regard to the quantity of water that can be realised from a given rainfall. The rain available for gravitation waterworks, more particularly when a large proportion of the water is from springs, falls almost entirely in the *winter months*, and a deficiency in *winter* rains, although the whole year's rain may be equal to or greater than the average fall of the district, occasions a falling off in the quantity of water in the streams and springs. This is more particularly the case when two or three *dry winters* follow in succession, and the quantity of water realized from a given rainfall of one such year does not apply to the second, which produces a still smaller proportion—for instance, at Liverpool (as reported by the Corporation Engineer), "in 1862 the rainfall was "48·51 inches, the ratio of impounded water to the rain-"fall was 82·63 per cent. In 1865, when the rainfall was "34·8 inches, the proportion of available water flowing off "was only 67·12 per cent.; so that, apart from the "deficient rainfall, that which did fall yielded less by "15·51 per cent. than the rainfall of 1862." Again, at Newcastle, a rainfall of 26 or 27 inches; that is, two or three inches above the average, produces water to the extent of somewhere about 60 per cent. of the fall, while in the year 1850, in which 17·68 inches only fell, the proportion realized was only 6¼ inches, or 35 per cent. of the fall.

Thus, it appears that, basing calculations on *average* falls of rain is erroneous; the minimum quantities only should be depended upon; but, as I have before stated, there is yet no experience sufficient to show what are the minimum falls in a given district, nor what proportion of such falls would be available.

The question of storage is, of course, an important element in gravitation works, and from past experience it is plain that complete security against want of water in exceptionally dry years, could only be attained by storing all the flood waters of two or three successive winters, or, in other words, providing storage for 300 or 400 days' supply to the district.

This matter was well explained by Mr. Homersham, C.E., in a report on the supply of water to Manchester in 1848, in which he states generally that if the whole quantity of water collected in wet years be not used, then the quantity of water that could be regularly yielded by the reservoirs would depend upon the depth of rain falling on the gathering ground and flowing off it in the *average* of years, since the water falling in wet years would be stored from wet to dry years. The size of such reservoirs must, however, be *very large*, as they must be sufficient to contain the superabundance of a succession of wet years, in order to compensate for the deficiency of a succession of dry ones.

The axiom in mechanics, that the strength of a beam is the strength only of its weakest part, applies also to gravitation waterworks, their real strength or power of supply being only the *minimum quantity they may be reduced to*. To be absolutely safe for all periods, it would appear that they ought to be made capable of supplying in years of average rainfall twice the quantity of water required, in order to be equal to meet the deficiency of a minimum year.

I am, &c.
John Taylor.

Great George Street, Westminster,
9th June 1868.

APPENDIX BC.

Report on the Drought of 1868 as regards its Effects on Gravitation Water Supplies to Large Towns.

To the Chairmen of the London Water Companies.

Gentlemen,

In pursuance of instructions received from you on the 16th ult., to inquire into the effects of the late dry season on gravitation water supplies obtained from water-sheds or drainage grounds, I visited various towns reported to have suffered from deficient water supply during the summer and autumn of the present year, and have to lay before you the following results of my investigation:—

Manchester.

Towards the end of July the corporation of Manchester became alarmed at the prospect of a failure in the water supply, and issued the following public notice:—

"*Manchester Corporation Waterworks.*—Tubes for watering gardens and other purposes.—In consequence of the number of persons who are illegally using tubes, for watering gardens and other purposes, notice is hereby given, that under the provisions of the Manchester Corporation Waterworks Act, all persons using such tubes without having made an express agreement in writing with the corporation, are liable to a penalty of 40*s.* for each offence, and that the penalties will in all cases be strictly enforced.

"By order (signed) Joseph Heron, Town Clerk,
"Town Hall, Manchester, July 24, 1868."

The "Manchester Courier" of August 1, contained an appeal to the water consumers as follows:—

"*The Water Supply of Manchester.*—We have been requested by the mayor to publish the following:—The extraordinary and unlooked-for continuation of the heat and drought has compelled the Waterworks Committee carefully to consider their position, and the expediency of taking steps to economise the consumption of water, and to ward off the possibility of any absolute failure in the supply. Every individual is deeply interested in and bound to aid the corporation in successfully accomplishing their object. We understand that it has been decided at an early period (of which, however, public notice will be given) to stop the supply of water during the night; and also to make, if possible, an amicable arrangement for a reduction in the quantity of water daily sent down the river; and it has also been decided to recommend that the watering of the streets shall for the present be entirely discontinued. There is, we are glad to believe, no ground whatever for any alarm; nor, with the aid and co-operation of the inhabitants generally—which, if only out of gratitude for the blessings heretofore enjoyed, the corporation have a right to expect—need there be the least apprehension that any but comparatively trifling inconvenience will be sustained as the consequence of the present extraordinary season. The inhabitants may rely upon having water during, at any rate, 12 hours of each day, and therefore there will be no cause whatever—nor indeed any excuse—for any waste, by making other than the smallest provision for the time when the water may be off. It needs hardly to be pointed out that the use of water for any purpose not absolutely required (such, in fact, as baths, watering gardens, and many other purposes) ought for the present to be discontinued. Every individual is deeply interested in the success of the efforts being made by the corporation to guard against the possibility of there being any interference with such a supply of water as may be absolutely required for the comfort and health of the inhabitants."

In pursuance of this general intimation to the inhabitants of Manchester, the following official public notice was issued the week following:—

"*Manchester Corporation Waterworks.—Public Notice.*—Notice is hereby given, that in consequence of the unprecedented and still-continuing *drought*, the Waterworks Committee have, in addition to other steps being taken for economising the consumption, determined that on and after Monday the 3d day of August inst., and until further notice, *water* shall be supplied only between the hours of six o'clock in the morning and six o'clock in the evening of each day, within the limits of the supply of the Manchester Corporation.

"The committee consider that it is their paramount duty, even at the risk of some present inconvenience, to guard against the possibility of their being unable to supply to the inhabitants the water absolutely required for health and comfort; and they confidently appeal to all to assist them in economising in every way the consumption; and, as the water will be certainly supplied during the hours named, not to cause waste by making undue and unnecessary provision for possible requirements during the time the ordinary supply will cease.

"Dated this 1st day of August 1868.
"By order of the Waterworks Committee.
"(Signed) Joseph Heron, Town Clerk."

In addition to the restrictions in the use of water above alluded to, viz., stopping the street watering and limiting the time of supply to 12 hours per day, the Waterworks Committee effected an arrangement with the mill-owners on the river Etherow to reduce the quantity of compensation water daily delivered from the store reservoirs for uses of the mills, from 15,000,000 of gallons per day to about 7,000,000 of gallons per day, thus conserving for the use of the town nearly 8,000,000 of gallons per day. This arrangement commenced from 10th August, and continued in force for about eight weeks, during which time 384,000,000 of gallons were brought from the mills for the use of the Manchester Waterworks district.

Notwithstanding, however, this limitation to the mills, the store of water continued to decrease, and the following notices were issued to large consumers:—

"*Town Hall, Manchester, August 4th*, 1868.—I am directed by the Waterworks Committee to inform you that in consequence of the present unprecedented drought, the supply of water to your works will be diminished to one-half the quantity that you used during the last quarter. I send you this communication in order that your business arrangements may be as little interfered with as possible.
"(Signed) Joseph Heron."

The principal hotels in Manchester were also cautioned upon the subject, and the following notice was posted in all the bedrooms of the Queen's Hotel:—

"*Notice.*—Owing to the scarcity of water, visitors are respectfully requested not to waste any. Sponge baths one shilling; all other baths will be discontinued."

About the middle of September, it was reported that the store reservoirs, notwithstanding the restricted consumption, both to the mills and the town, contained only about five weeks' supply, and the Waterworks Committee issued the following notice, dated 17th Sept.:—

"*Manchester Corporation Waterworks.—Public Notice.*—Notice is hereby given that in consequence of the still-continuing drought, the Waterworks Committee have, in addition to other steps being taken for economising the consumption, determined that on and after Monday, the 21st September inst., and until further notice, water shall, within the limits of supply of the corporation, be supplied only between the hours of six o'clock in the morning and two o'clock in the afternoon of each day. In order to guard against the possibility of their being unable to supply the inhabitants the water absolutely required for health and comfort, the Waterworks Committee again confidently appeal to all to assist them in economising in every way the consumption; to use any pumps or other sources of supply which may in any case be available; and not to cause waste by making undue and unnecessary provision for possible requirements during the time the ordinary supply will cease.

"Dated this 17th day of September 1868.
"By order of the Waterworks Committee.
"(Signed) Joseph Heron, Town Clerk."

Again, on the 19th September, the Waterworks Committee issued the following circular:—

"*Supply of Water in Manchester.*—The drought still continues, and it has long ceased to be possible to anticipate or speculate with any degree of certainty as to the time when we shall have in this district any rainfall which will materially increase the storage in the corporation reservoirs, upon which so enormous a population is dependent for the supply of water absolutely necessary for health and comfort.

"The drought has now, with little or no material interruption, continued for the unprecedented period of nearly six months, and it is hardly necessary to say that the Waterworks Committee have, for many weeks past, been compelled to consider in what way the consumption can be reduced, and been watching with the greatest anxiety the gradual but constant diminution of the water in the reservoirs.

"As already announced, one half only of the compensation water required to be sent down the Etherow for the supply of the mills has for some weeks been furnished. A further reduction may become necessary, but unless and until absolutely compelled, the committee are most unwilling further to interfere with such supply. The committee

have every reason to be satisfied with the disposition generally manifested by the occupiers of the mills for whose benefit such compensation water is secured by Act of Parliament, in every way to meet the corporation under circumstances of unprecedented difficulty, fully recognizing the fact that, without abandoning their claims to reasonable compensation for any actual loss or extra expense sustained, the supply of water for the requirements of the inhabitants for domestic consumption must and ought to be the paramount consideration with the corporation.

"At a meeting of the committee held yesterday it was determined to shorten the hours of supply, and to supply water throughout the city and district dependent upon the corporation, from and after Monday next the 21st instant, only between the hours of six o'clock in the morning and two o'clock in the afternoon; and at the same time still further to reduce the quantities of water supplied for trading purposes.

"When the inhabitants consider the reports appearing constantly in the papers of the very short period (varying from one or two to three or four hours) during which water is supplied to the inhabitants in neighbouring towns, and in other cases of the entire failure of all supply by the authorities, they have every reason to congratulate themselves that the corporation are after such a period of drought, and notwithstanding the large demands upon their works, still able to propose to supply water during eight hours of each day, and thereby to afford an ample opportunity to all to obtain the quantity of water absolutely required. How long this great boon may continue in the possession of the inhabitants will, if the drought continue, to a great extent depend upon themselves. The utmost economy in the use of water must be exercised. Where any other means of supply, either from existing pumps or otherwise, are available, such means ought to the largest extent possible to be made use of, in order to lessen the consumption of the water of the corporation.

"The committee have every reason to believe, from the diminished consumption which has resulted from the shortening of the hours of supply, that the inhabitants have willingly and effectively carried out the desire of the corporation, that they should exercise the strictest economy in the use of the water; and with such continued co-operation and assistance, the committee trust that they may yet be enabled to pass through this most extraordinary ordeal without limiting to a greater extent than is now proposed the supply of water to the inhabitants."

Amongst other steps taken by the Waterworks Committee for conserving the water, was the putting in force of the provisions of their Acts of Parliament against the waste and misuse of water by the inhabitants, as indicated in the following paragraph, which appeared in the "Manchester Courier" of August 6:—

"*Wasting Water in Manchester.*—Twenty-two cases of offences against the Waterworks Acts were heard by the Waterworks Committee of the Manchester Council on Monday last, of which three were fined for using tubes for watering gardens without agreement, six for taking water illegally, two agreed to take the water, one excused, one plumber struck off the list, one consumer cautioned against waste, two reprimanded, one adjourned for further inquiry, four for wasting water by tubes being left running on the grass, and one for further inspection. Total amount of penalties, 16*l.* 15*s.*"

Again, in the paper of August 19th, it was reported as follows:—

"*Misuse of Water in Manchester.*—Eleven persons were brought before the Manchester Waterworks Committee on Monday for offences against the Waterworks Acts, of which six were fined for using tubes for watering gardens and other purposes without having made agreements, and two for obtaining water illegally; one agreed to take water, one plumber was authorized, and one suspended. Total amount of penalties, 7*l.* 0*s.* 4*d.*"

These proceedings, although there can be no question as to their propriety at the time, serve to show the exigencies of the case, and the stringency of regulations the enforcement of which we are as yet happily ignorant of in London.

The limitation of the supply to eight hours daily continued in force from 21st to 29th September, when the 12 hours' supply was again resorted to, and this continued to the 26th October, when the full supply was afforded to the district. Thus, for 76 days it was limited to 12 hours per day, and for seven days to eight hours per day.

The ordinary supply to the Manchester district, which includes besides the towns of Manchester and Salford a large outlying population extending to many neighbouring towns, averages about 15 million gallons per day, and the compensation water sent down the river Etherow is nearly 15 millions per working day, and spreading the latter over seven days per week, the average daily draught from the works is about 27 million gallons per day. It is difficult to ascertain the exact quantity during the limited supply, but from data obtained I estimate that during the 12 hours' limitation the district supply was reduced from 15 millions to about 11 millions per day, and during the eight hours' supply to about 8 millions of gallons per day, or about 13½ gallons per head per day of the population for all purposes, including the limited supply to manufactories.

When the restriction to the mills took place 8 millions of gallons per day were reserved from compensation water for the district supply, and upon these data it appears that the total deficiency of the ordinary supply of water from the Manchester Gravitation Works was 737 million gallons spread over 83 days, or nearly 9 million gallons per day.

It should be mentioned that the quantities distributed, as above stated, were increased to the extent of about 550,000 gallons per day pumped from the old well at Gorton, which was put in requisition in aid of the gravitation supply from 12th August to 8th October.

The two new compensation reservoirs in course of construction below Rhodes Wood reservoir, alluded to in my former report, are designed to hold 750 million gallons of water; it would therefore appear that had these reservoirs been filled before the commencement of the drought the full compensation water to the mills could have been sustained throughout, and a further quantity been available for the district supply.

It does not appear that the restriction of the hours of supply caused any serious want of water for purely domestic use; on the contrary, it is believed that more water than usual was consumed in the houses of the middle and lower classes, where no cisterns existed for storing the day's supply, and for this reason—that during the known hours of service all available receptacles for water were filled and kept in reserve for night use, and thus generally a superabundant provision was made, which was thrown away next day when the water was again turned on at the mains. The deficiency was chiefly observable in the curtailment of the comforts and benefits attending the ample use of water for street watering and for washing courts, and for other sanitary purposes, and for watering gardens, for private baths, waterclosets, and domestic washing; and in such curtailment, together with the saving of night waste and the diminished supply to large consumers, lay the real saving of water during the limited supply. Had a cistern existed in every house, all the trouble and annoyance attending the temporary storage of water in every variety of receptacle would have been avoided.

Salford.

The borough of Salford is supplied with water from the Manchester Works, the water being measured and charged by meter to the corporation. The water district comprises about 77,000 inhabitants, and the usual supply is about 1¾ millions per day, or about 22 gallons per head per day for all purposes. The domestic supply is stated to be about 15 gallons per head per day.

The water service was restricted in Salford at the same times and to the same hours per day as in Manchester, public notices to that effect being issued. The restriction to 12 hours per day reduced the quantity from 1¾ millions to 1¼ millions per day, and for eight hours per day service the quantity was reduced to about 900,000 gallons, or 13½ gallons per head per day for all purposes. The same remarks on the domestic supply during the restricted hours of service apply to Salford as well as Manchester; but seeing that the whole supply was reduced to 13½ gallons per head per day for all purposes, and that the manufacturers had no other limitation than the hours of supply, the purely domestic service must have been reduced to eight or nine gallons per head.

Stockport.

Stockport is supplied with water partly from a watershed and store reservoir in Lyme Park, about six miles distant, and partly from the Manchester Works under an agreement with the corporation to provide any quantity of water required, not exceeding 1 million gallons per day. The full supply to Stockport is about 1½ million gallons per day to 60,000 persons, or 25 gallons per head per day for all purposes.

The drought was felt equally at Stockport as at Manchester, and the water service was restricted about the same times and to the same hours as in that district. The following public notice was issued:—

"*Stockport District Waterworks Company.—Public Notice.*—Notice is hereby given that owing to the long continuance of the drought, without any appearance of its cessation, it is incumbent on all parties to economise the use of water; and if the inhabitants will restrict themselves to the use of *six or seven gallons a head per day*, the

company will be enabled to supply them, no matter how long the drought continues. But in order to ensure a diminution in the quantity of water used, they must discontinue the supply at night, and probably during a portion of the day, if it is found that the water used still exceeds the quantity named. On and after Thursday the 6th day of August instant, and until further notice, water will be supplied between the hours of 7 o'clock in the morning and 7 o'clock in the evening of each day. The company trust the inhabitants will assist in every way in economising the consumption.

"Dated this 5th day of August 1868.

"By order, GEORGE MATHER, Secretary."

In the course of September it became apparent that the Lyme Park store would fail, and the quantity supplied by the Manchester corporation being reduced to about 200,000 gallons per day, recourse was had to wells existing at two old pumping stations near the town, from which a part of the original supply of water to Stockport was obtained, and from these wells a limited quantity per day was pumped in aid of the supply from the Manchester Works.

ROCHDALE.

The Rochdale Gravitation Works supply a population of about 40,000, with an ordinary supply of about 750,000 gallons per day, or 18¾ gallons per head per day, there being few meter supplies, and only about 400 waterclosets, out of 13,000 services. The capacity of the four store reservoirs attached to the works is 172 million gallons, but in March last the largest, containing when full 47 million gallons, became defective, and the water was run off, so that the summer store was considerably reduced; the gathering ground is from 600 to 700 acres in extent.

In apprehension of the effects of the drought, the following notice was placarded about the town:—

"*Rochdale Water.*—Notice is hereby given, that during the droughty weather now prevailing, *a supply of water* from the Rochdale Corporation Waterworks will be afforded between the hours of 7 *and* 11 *o'clock in the forenoon only* of every day after Friday next.

"By order, ZACH. MELLOR, Town Clerk.

"Rochdale, 25th June 1868."

Notwithstanding the restriction of the water supply as above intimated to four hours only per day, which continued for about 15 weeks, the store of water was entirely exhausted during the second week in October, and the town would have been almost without water, but that recourse was had to pumping from Dearnley Colliery, about two miles from Rochdale. This temporary source was sufficient to keep the town supplied with water for domestic wants.

An extension Act was obtained in 1866, and additional works are in course of construction.

BURY.

The town of Bury is supplied with water by the Bury and Ratcliffe Waterworks Company. The inhabitants supplied number about 60,000, and the ordinary quantity of water consumed is rather less than 1 million gallons per day, or 16⅔ gallons per head per day, there being few waterclosets, and little street watering. There are four store reservoirs attached to the works, having a capacity of 275 million gallons, with a water-shed of about 2,000 acres. Compensation water to mills is given out of this store to the extent of 1½ million gallons per day, so that with the town supply the full draught is nearly 2½ million gallons per day, and at this rate the reservoirs hold a little over 100 days' supply.

The store of water ran so low towards the end of August that it was reserved entirely for compensation to the mills, as the company were able to obtain from a neighbouring works (the Haslingden and Rawtenstall Water Company) a supply of 400,000 gallons per day for the town of Bury. This provided a quantity of rather less than seven gallons per head per day, which sufficed to supply purely domestic wants; but for baths, manufacturing, or trade uses there was no water. This must have been severely felt by manufacturers, as in ordinary times a good deal of water is taken for steam purposes and dyeing. The company were enabled to continue the full compensation water to the mills, and thus avoid the payment of penalties; but at the lowest water time there were not more than two or three days' water left in store. The short supply of water to the town continued for five weeks.

BOLTON.

The population of Bolton supplied with water is about 100,000, and the ordinary quantity supplied about 2,500,000 per day, or about 25 gallons per head per day for all purposes. There are four store reservoirs belonging to the works, having a combined capacity of 300,000,000 gallons, or 120 days' supply.

The supply to the town was reduced on the 9th September to one-half the ordinary quantity, and continued so till the 12th October, or about five weeks. The service was not limited to any stated time, but was given out at the discretion of the engineer, in different parts of the town, at different hours of the day, in the manner of an intermittent supply. No public notices were issued.

The compensation water to the mills is given from separate reservoirs for that purpose only, which are under the control of the millers.

LIVERPOOL.

Liverpool is supplied with water on what may be called the *mixed* system, partly from the Rivington Gravitation Works, and partly from a number of wells in the more immediate neighbourhood, sunk into and deriving water from the new red sandstone.

By a recent Act of Parliament the corporation are authorized to shut off the water at any time, as circumstances require, and during the whole of this year the district has not had more than 12 hours per day supply of water; in fact the supply is now practically intermittent. Notwithstanding this, however, the drought was seriously felt, and on the 22d August the service was limited to nine hours per day, and again, about the 9th of September, to seven hours only per day, at which it was still maintained at the date of my inquiry (31st October).

The quantity of water supplied before the limitation to nine hours' service was about 16,500,000 gallons, or about 27 gallons per head per day, of which about 6,000,000 were pumped from the wells, and 10,500,000 provided from the gravitation works.

The quantity of water supplied after the limitation of service to seven hours per day was about 13,000,000 gallons (or 21 gallons per head per day), of which 7,000,000 were supplied from the gravitation works.

The compensation water afforded to rivers and mills was originally 8,300,000 gallons per day continuously, but since September last year it has been reduced to about 6,500,000 per day, by the purchase of 1,850,000 gallons per day, and this additional quantity has thus been available during the late dry season.

The present full store of water at Rivington is 3,100 million gallons, and the quantity was reduced in the drought down to 700 millions, or, including the compensation, to about 50 days' supply of the quantity consumed during the seven hours' service.

Liverpool has not seriously suffered from the drought; the domestic supplies have been influenced in the same manner as described in Manchester, by the consumers making provision against the shutting off of the water by the temporary expedients of storing in tubs, &c. The limitation of the hours of service to seven per day only reduced the consumption by about 3½ million gallons, and could the extent of the drought have been foreseen, the 12 hours' supply might have been continued throughout the entire season, without altogether exhausting the gravitation store of water.

PRESTON.

The town of Preston, containing a population of about 93,000 inhabitants, is supplied with water from a gravitation work in the hands of the corporation. The storage reservoirs, three in number, have a total capacity of 265 million gallons, with a drainage ground of 2,878 acres. The ordinary summer supply to the town is about 2¼ million gallons, or 24 gallons per head per day for all purposes, or 18 gallons per head per day, exclusive of trade supplies. The store reservoirs, therefore, contain about 120 days' supply of water. At the end of June fears were entertained of the reservoirs running dry, and a temporary source of supply was looked for. At the end of July it was estimated that only 23 days' water was left in store, and the Water Committee confirmed the proposed arrangement for pumping water from the river Hodder, a tributary of the Ribble. In about three weeks the temporary works were brought to bear, and the pumping was commenced on 27th August, at which time the reservoirs were practically dry. These works were costly, as the temporary source of supply was 13 miles distant from Preston, and pipes and open cutting for that length of aqueduct, besides the steam engines and pumps, had to be resorted to. The water was lifted 120 feet from the river, and then flowed through the temporary aqueduct to one of the store reservoirs, and the quantity pumped was sufficient to maintain the supply of the town, which was thus continued constantly throughout the drought. The pumping was carried on from 27th August to 24th October, or 58 days.

Notice of application to Parliament for extension of works is given for the ensuing session.

Kendal.

This town is supplied with water from a gravitation work belonging to the Kendal Gas and Water Company. The population is about 12,000, and the works consist of two store reservoirs, with a joint capacity of 32 million gallons, and a drainage ground of 240 acres, entirely devoted to the town service. The ordinary quantity supplied is 200,000 gallons, or 16⅔ gallons per head per day, and the full store contains 160 days' supply.

On 19th August the reservoirs were exhausted, and the town was left without any supply of water for four or five days. A temporary pumping work to supply water from the river Kent, about a mile and a half above the town, was then hastily carried out, and about 160,000 gallons per day thus provided; and this means of supply was continued for five weeks. I was informed that the company contemplate making a permanent pumping work from the river, in aid of the gravitation supply during seasons of drought.

Newcastle-on-Tyne.

The Newcastle and Gateshead Water Company now supply their district on the mixed system, viz., from the Whittle Dean Gravitation Works, and from the new pumping works lately established near Newburn, to pump water from the river Tyne above tidal influence. The district has not been short of water, because the deficiency of the gravitation supply was made up from the pumping works. The quantity ordinarily supplied at present is 5½ to 6 million gallons per day, to a population of 170,000 to 180,000 people, or about 32 gallons per head per day.

The service throughout the drought has been 3 millions of gallons, drawn from Whittle Deen store reservoirs, and 3 millions pumped from Newburn. With this draught upon the reservoirs they have been reduced from the full capacity of 530 million gallons to 78 million gallons, the decrease in the store continuing down to the 2d November, notwithstanding the rains of September and October.

The supply of water from these gravitation works failed during the drought of 1857 and 1858, as alluded to in my former report, the deficiency of water being then temporarily made up by pumping from the Tyne. The drainage ground has, from time to time, been increased to upwards of 17,000 acres, but even with this increase, the gravitation supply alone would have failed to afford a full supply to the district for many weeks during the present summer and autumn; this being proved by the fact that a draught of 3 millions per day reduced the store to only 25 days' supply, and, as a matter of course, a draught of 5½ millions would have exhausted it early in the summer

Bradford.

The population of Bradford within the limits of the water district is 250,000, of which about 150,000 only are present supplied from the works, viz., 90,000 on the low level, and 60,000 on the upper level. The present storage capacity of the reservoirs attached to these gravitation works is 300 million gallons for the low level, and 85 millions only for the upper level, the water being gathered from 9,000 acres for the low, and 900 acres for the upper level. It will be convenient to allude to these as two separate water supplies, as they failed at different periods, the higher level suffering much more than the lower.

The low-level district has an ordinary supply of 4½ million gallons per day in winter and 6 millions in summer, say 5½ millions per day average; and thus the low-level storage is equal to about 160 days' supply. About the middle of June it became doubtful whether the full supply could be maintained, and the quantity was diminished successively to 4½, 3, and 2 million gallons per day, the latter being supplied in six hours only, to which the time of service was gradually diminished.

The upper-level district has an ordinary supply of 1 to 1½ million gallons for winter and summer respectively; and the storage capacity for this is therefore only about 68 days' water. On 19th June this store was practically exhausted, and the reservoir was shut off on 20th June, and during the following 16 weeks the water was only turned on once a week (on Saturdays), the quantity accumulated during the week being then distributed—a quantity equal to about a full day's supply.

No compensation water for mills was given out of the town reservoirs, as there are separate reservoirs for this purpose under the control of the millers themselves.

The following public notices were issued:—

"*Bradford Waterworks.—Public Notice.*—In consequence of the long-continued dry season, the store of water in the Stubden reservoir has been so much reduced, that the full and regular supply of water throughout the high-level district cannot be continued. The water will be shut off on Saturday, 20th June instant, and will be turned on again on the Saturday following, and on every succeeding Saturday only, so long as the dry season continues. The places to which this notice applies are the high-level parts of the borough—Thornton, North Bierly, Wibsey, Gomersal, Birstal Tong, Tyersal, Pudsey, and Eccleshill.

"By order, Charles Gott, Waterworks Manager.
"19th June 1868."

"*Bradford Waterworks.—Public Notice.*—In consequence of the continued dry season, and the diminished supply of water to the reservoir, the Waterworks Committee are under the necessity of urging upon all consumers of water to take every precaution to prevent *any waste of water*. And they are furthermore obliged to prohibit, from the date hereof, the use of any portable pipes or other means for the purpose of *watering gardens, washing causeways, windows*, or any similar use.

"All persons are hereby requested to give information at this office of any waste of water being permitted, or of any such use for the aforesaid purposes of gutta percha or other pipes. It is hoped that there will be no failure in the supply throughout the low-level district, if proper care is taken by the consumers, but that, of course, will be dependent on the length of time the dry weather may still continue.

"By order, Charles Gott, Waterworks Manager.
"Waterworks Office, June 26th, 1868."

"*Bradford Waterworks.—Caution as to the use of Water.*—The Waterworks Committee feel compelled, in consequence of the continuation of the drought, to call attention to the necessity for extreme caution in the use of water throughout those parts of the district which are supplied from the low-level service.

"The committee regret that there has been cause for reports to be made to them of the unnecessary use of water by several persons in the town, notwithstanding the previous notices.

"The committee request every person to exercise the greatest care in the use of water, not only to prevent waste, but also to limit its use to purposes of absolute necessity.

"The committee have reason to hope that with the co-operation of the inhabitants, and with the exercise of care on the part of every consumer, they will still be able to maintain the supply throughout the dry season.

"By order, Charles Gott, Waterworks Manager.
"July 1868."

"*Bradford Waterworks.—Notice as to the use of Water.*—The Waterworks Committee feel it to be their duty to make a further appeal to the inhabitants generally to reduce the consumption of water throughout the town and district—both for domestic use and for trade purposes—to the smallest quantity practicable.

"The reduction in the use of water, and the care which has been taken since the previous notices, have had the effect of enabling the committee to continue the supply up to the present time without interruption, and the committee still hope that, *with a further effort on the part of the inhabitants*, a failure of the supply will be entirely avoided.

"It is also very important that everyone should be careful to keep their water taps and fittings in good repair, to prevent the loss of water from waste.

"By order, Charles Gott, Waterworks Manager.
"Swaine Street, 11th August 1868."

The town of Bradford has, therefore, had 60,000 of its inhabitants reduced to one day's water supply per week, for 16 weeks, and 90,000 reduced gradually, during the same period, down to six hours' supply per day, which continued for five or six weeks. A great deal of water is ordinarily supplied for manufacturing purposes, which of course have been most seriously affected. These waterworks have only been in operation for eight years, and have not before failed; new reservoirs are now in course of construction, and notices are issued for application to parliament for further extension of works.

Halifax.

The town of Halifax is supplied with water from gravitation works in the hands of the corporation, the population supplied being about 50,000. The reservoir capacity is 280 millions of gallons, and the ordinary supply to the district is 1½ to 2 million gallons per day, a large quantity of water being supplied for manufacturing purposes. Compensation water for mills, to the extent of 1 million gallons per day, is given out of the Ogden reservoir, under heavy pecuniary penalties in case of failure. Thus the total draught on the works in ordinary times is nearly 3 million gallons per day, and the full store of water is therefore equal to about 100 days' supply.

In the month of May the drought was beginning to be felt, and the store of water to be reduced; and the Waterworks Committee on 11th resolved to limit the domestic supply to 14 hours per day, viz., from 5 a.m. to 7 p.m., and to restrict the trade supply to not more than 30,000 gallons per day to each consumer.

On the 19th May it was further resolved to limit the trade consumers to 15,000 gallons per day each, which con-

tinued to the 29th June, when it was again resolved to limit them to 3,000 gallons only per day each.

On the 14th July the following public notice was issued, to limit the domestic supply to 10 hours per day, a resolution of the committee being passed at the same time to further reduce all trade supplies to 2,000 gallons per day to each consumer:—

"*Halifax Waterworks.—Notice* is hereby given that on and after the 16th instant the supply of *water for domestic purposes* will be limited to 10 hours per day, namely, from the hour of 5 o'clock in the morning until 3 o'clock in the afternoon. Persons having boilers in connection with kitchen ranges are warned not to allow such boilers to become empty, in order to avoid explosion.

"The public are cautioned against the *waste of water*, and the use of the hose and jet is strictly prohibited.

"Persons disobeying this order render themselves liable to heavy penalties.

"By order, JAMES EDWARD NORRIS, Town Clerk.
"Town Hall, Halifax, 14th July 1868."

Ten days later, viz., on 25th July, it was resolved to limit trade consumption to 1,000 gallons per day to each consumer, the probability of the total suspension of such supplies being threatened; and the following public notice was also issued, limiting the time of domestic service of water to six hours per day, namely, from 10 a.m. to 4 p.m.:—

"*Halifax Corporation Waterworks.—Caution.*—Notice is hereby given, that on and after to-morrow, the 26th July instant, the supply of *water for domestic purposes* will be limited *to six hours per day*, namely, from 10 a.m. to 4 p.m.

"The public are earnestly requested to co-operate with the authorities in economising water as much as possible. Any person wilfully wasting water will be punished as the law directs.

"By order, JAMES EDWARD NORRIS, Town Clerk.
"Town Hall, Halifax, 25th July 1868."

Thus the domestic supply of water was limited to 14 hours per day for 66 days, to 10 hours per day for 10 days, and to six hours per day for 86 days, the full supply being only resumed on 19th October; while the supply to large consumers for the important trade of this district was gradually reduced from the first limit of 30,000 gallons per day to 1,000 gallons per day each.

The full compensation water to the mills was continued throughout, and pecuniary penalties avoided; but, on 22d September the entire store of water was reduced to about 22 million gallons, that of the Ogden reservoir being only 11½ millions; so that, apart from the town supply, there were only about 11 days' compensation water left.

On the 28th July a small stream of water began to be used as a temporary aid to the general supply.

The works are now in course of extension, under the powers of an Act of Parliament procured in the session of this present year.

SHEFFIELD.

The population of the town and district of Sheffield supplied with water by the Sheffield Waterworks Company is 210,000, and the ordinary quantity supplied is about 3,800,000 gallons, or 18 gallons per head per day.

The total capacity of the storage reservoirs is 900 million gallons, with a drainage ground of 4,461 acres. The quantity of water given out of the reservoirs for mill compensations is 3,250,000 gallons per day, making the total ordinary draught from them 7 millions of gallons per day, or thereabouts; the full store of water is therefore equal to 128 days' supply.

Sheffield, although supplied by gravitation works, has at no time more than an intermittent service of 12 hours per day, and early in June the drought made it apparent that this could not be prudently maintained, and the hours of service were, on 9th of that month, reduced from 12 to 10. On July 6th the hours of service were further curtailed from 10 to eight, and on August 12th from eight to six; and lastly, on September 2d, from six to four hours' supply per day, the Sunday supply being discontinued on and after September 6th (as per notice below). The quantity of water supplied to the district was at this time reduced from 18 gallons to 11·3 gallons per head per day; and the compensation water to the mills was also reduced during the whole of September to one half the ordinary delivery. Notwithstanding these reductions in the consumption, the store of water became reduced in September to 128 millions of gallons, or 32 days' supply only of the *reduced* quantities, both to the district and the mills.

The following public notices were issued:—

"*Water Supply.*—The stock of water in the storage reservoirs for the use of the town having become so very much reduced in consequence of the unusual drought of this season, the Directors of the Water Company most earnestly request that all consumers will abstain from using the water for any other purposes than those which are absolutely necessary. The Directors think right to give notice that should the present dry weather continue, it will shortly be necessary to restrict the supply of water to three days a week.

"WILLIAM WATERFALL, Managing Director.
"10th August 1868."

"*Water Supply.*—The stock of water in the storage reservoirs for the use of the town having become very much reduced, in consequence of the unusual drought of this season, the Directors of the Water Company, in order to economise the water as far as practicable, have determined to discontinue the supply to the town on Sundays, believing that the absence of water on those days will cause less inconvenience to consumers than restrictions on the working days of the week.

"Notice is therefore hereby given, that the water will not, for the present, be supplied on Sundays.

"The Directors also think right to give notice that, should the present dry weather continue, it will shortly be necessary to restrict the supply of water to three days a week, and the Directors most earnestly request that all consumers will abstain from using the water for any other purposes than those which are absolutely necessary.

"WILLIAM WATERFALL, Managing Director.
"31st August 1868."

The supply to manufacturers was not curtailed beyond the hours of reduced service throughout the district. As the store of water increased, the time of service was lengthened, but the regular supply of 12 hours per day was only resumed on the 9th instant.

Although the hours of service were reduced during September and part of October to one-third or 33 per cent. of the ordinary time, the quantity of water supplied was only reduced from 18 to 11·3 gallons per head per day or 62½ per cent. The supply for purely domestic purposes was therefore not greatly curtailed in quantity, but was attended with all the evils and inconveniences to the consumers before alluded to in the case of Manchester. In fact, in the absence of cisterns for storage, all the towns put on short supply must have been similarly circumstanced as regards the domestic services.

The Sheffield Waterworks have for some years past been in course of extension.

OTHER TOWNS.

In addition to the towns particularly alluded to herein, many others have suffered to a greater or less extent from deficient water supply during the drought of the present year, amongst which may be mentioned Ashton, Staleybridge, Mottram, Oldham, Dewsbury, Warrington, Blackburn, Bacup, Burnley, and Newport in Monmouthshire. Of these towns, however, I have not obtained precise information.

GENERAL REMARKS.

With regard to the rainfall of the present year, the average for 13 localities in the counties of Lancashire, Cheshire, Cumberland, Northumberland, and Yorkshire, for the last 10 months to end of October, has been about 30 inches; and, comparing the results of this year with the averages of the corresponding 10 months for many years past, at places for which I have been able to get such returns, I find the rainfall has been deficient in the proportion of about 40½ inches to 34½ inches, or 85 per cent. of the average. This deficiency, however, does not in itself altogether account for the extraordinary drought that has prevailed, because during the first three months of the present year the rainfall was generally more than an average. It was the singular deficiency of rain in May, June, and July, accompanied with an excess of temperature and evaporation, that caused the exhaustion of the springs, streams, rivers, and stores of water throughout the country.

The general result has been that nearly all gravitation supplies of water, obtained from drainage grounds, have failed in a manner hitherto unprecedented within the known experience of such works, proving that the data on which they have been based have been fallacious, and that the storage reservoirs and gathering grounds of such works must be greatly increased to meet the demands of years like the present.

I am, &c.,
JOHN TAYLOR.

Great George Street, Westminster,

APPENDIX BE.

Supplementary Report on the Chemical Quality of Samples of Water collected in the Basin of the Thames.—By Dr. E. Frankland, F.R.S., and Dr. Odling, F.R.S.

To the Royal Commission on Water Supply.

My Lord Duke and Gentlemen,

In our previous report, your attention is called, at page 6, to the circumstance that the Thames is chemically purer at Hampton than at any other part of its course, and that between Staines and Hampton, a distance of only 12½ miles, the water of the Thames suffers a diminution of 3·33 parts of solid residue, of ·044 part of organic carbon, and of ·003 part of organic nitrogen in 100,000 parts of water. Two important tributaries, the Colne and the Wey, entering the river between the points at which the Staines and Hampton samples were taken, it appeared probable that the remarkable amelioration of Thames water between Staines and Hampton was due to one or both of these tributaries.

It hence seemed desirable to make a special investigation of this portion of the river, and, in accordance with your instructions, Mr. Pole collected the following samples on the 28th of October last:—

1. Water from the Thames just below Staines Weir, and above the junction of the Colne. Collected at 11.20 a.m. Temp. of water 8°·5 C.
2. Water from the main stream of the Colne, about 200 yards above its junction with the Thames. Collected at noon. Temp. of Water 8°·0 C.
3. Water from the Wey, about 200 yards below the entrance into it of the Basingstoke Canal, and about half-a-mile above its junction with the Thames. Collected at 2.45 p.m. Temp. of water, 8°·5 C.
4. Water from the Thames, just above the intake of the water companies at Hampton. Collected at 3.45 p.m. Temp. of water 9°·0 C.

The following table contains the results of the analysis of these samples.

	Thames at Staines.	Colne.	Wey.	Thames at Hampton.
Total solid residue from 100,000 parts of water evaporated and dried at 100° C.	31·40	32·14	18·10	29·90
Mineral substances in 100,000 parts of each water:				
Lime	12·63	13·78	5·73	11·85
Magnesia	0·70	·71	·52	·68
Potash	·56	·47	·52	·55
Soda	1·34	1·14	1·35	1·30

Carbonic acid	9·08	10·50	4·02	8·70
Silica	1·02	·99	1·17	1·21
Chlorine	1·66	1·59	1·83	1·76
Nitrogen as nitrates and nitrites	·173	·302	·090	·205
Ammonia	·004	·017	·005	·006
Organic substances in 100,000 parts of each water:				
Organic nitrogen	·097	·071	077	·057
,, carbon	·304	·282	·307	·263
Hardness in 100,000 parts of each water before boiling	22·0	21·7	10·1	21·6
Ditto after boiling	4·6	3·9	6·1	4·7

The reduced quantities of total solid residue and of mineral constituents in Thames water collected at Hampton, compared with the quantities found in the sample taken at Staines, are satisfactorily accounted for in the above analytical results. They are attributable chiefly to the Wey, which contains a much smaller proportion of these ingredients than does either the Thames or the Colne. On the other hand, the marked reduction of organic carbon and nitrogen, in the Thames between Staines and Hampton, finds no explanation from this supplementary series of analyses inasmuch as both tributaries contain these ingredients in larger proportions than does the sample of water collected at Hampton. As it was thus evident that the amelioration in question did not result from dilution, it was necessary to seek for its cause in chemical action. The effect might be attributed to an oxidation of the organic matter during the flow of the river from Staines to Hampton; but it was not likely that a process which had produced no corresponding effect between Lechlade and Staines should be able to bring about such a remarkable reduction of organic matter in the comparatively short distance of 12½ miles. Moreover there was another and obviously possible cause; viz., the incompatibility of certain kinds of organic matter with the hardening constituents of water—peaty matter, for instance, being rarely or never found abundantly in water containing much carbonate of lime; and we found on mixing a sample of water artificially contaminated by peaty matter with another sample in which bicarbonate of lime had been dissolved, that the mixture soon became slightly turbid, although each sample was previously clear and transparent. Acting upon the suggestion offered by this experiment, we mixed together equal volumes of the clear waters of the Thames at Staines, and of the Wey. Within half an hour the mixed sample had become perceptibly turbid, and after standing for 15 hours, a very marked brownish deposit had subsided to the bottom of the vessel. After filtration the mixed water was submitted to organic analysis. It yielded ·291 part of organic carbon and ·065 part of organic nitrogen. The difference between these numbers, and those yielded by the separate waters, is seen in the following table:

	Organic Carbon.	Organic Nitrogen.
1. 100,000 parts of Thames water collected at Staines and filtered contained	·304	·097
2. 100,000 parts of Wey water collected as described above and filtered contained	·307	·077
3. 100,000 parts of a mixture of equal parts of No. 1 and No. 2 ought to contain	·3055	·087
4. After standing 15 hours, the mixture, after filtration, actually contained	·291	·065
5. Removed from solution by mixture	·0145	·022

Although the reduction of organic matter here effected is not so great as that actually observed in the preceding series of analyses, yet it can scarcely be doubted that the result of our experiment points to the true cause of that greater reduction. It must also be borne in mind that the precipitation of organic matter would probably have been larger if the mixture, instead of standing for only 15 hours before filtration, had stood for a considerably longer time, as did the samples of Thames water from Hampton analysed by us on this and a former occasion. We believe that this mode of water purification has not before been noticed; it is, however, deserving the attention of the water engineer, and its importance is increased by the fact that the precipitated organic matter is highly nitrogenised, the proportion of nitrogen to carbon in the organic matter removed being 1·5 : 1 in the above experiment.

In conclusion, we give the following table, illustrating the difference in the composition of filtered Thames water at Staines and Hampton in spring and autumn.

Names of Substances found.	Sources of Samples.			
	Thames Water just below the Weir at Staines.		Thames Water at Hampton.	
	May 2d.	Oct. 28th.	May 4th.	Oct. 28th.
Total solid residue from 100,000 parts of water evaporated and dried at 100° C.	31·20	31·40	27·87	29·90
Mineral substances in 100,000 parts of each water:				
Ammonia	·000	·004	·000	·006
Nitrogen as nitrates and nitrites	·215	·173	·196	·205
Organic substances in 100,000 parts of each water:				
Organic nitrogen	·027	·097	·024	·057
„ carbon	·304	·304	·260	·263
Hardness in 100,000 parts of each water	20·8	22·0	20·0	21·6

It will be seen that the most important difference between the chemical condition of the Thames in autumn and in spring is that at the former season the soluble organic matter is more highly nitrogenised. This difference is seen from the following comparison:—

	Staines.		Hampton.	
	Spring.	Autumn.	Spring.	Autumn.
Proportion of organic nitrogen to organic carbon	1 : 11·2	1 : 3·13	1 : 10·8	1 : 4·61

We have the honour to be, &c.

E. Frankland.

APPENDIX BF.

Letter from the Engineer of the New River Company in explanation of his Answer to Question 3999.

New River Office, E.C.,
31st July 1868.

Dear Sir,

In reply to yours of the 29th instant, I have to explain that the amount returned as the aggregate yield of the New River Company's sources was made out thus:—

	Gallons.	
Average flow of the Chadwell spring	3,500,000	per diem.
Quantity which the New River Company are authorized to take, at all times, from the river Lea through their gauge at Hertford	22,500,000	„
Additional supplies from gathering ground at Cheshunt, &c.	500,000	„
Obtainable from six existing deep chalk wells, more than	8,000,000	„
Water collected in ponds at Hampstead and Highgate, and distributed through separate mains for watering roads, and other *non-domestic* purposes	500,000	„
	35,000,000	„

You will thus see that whatever supply may be obtained—

1. From a *new well* now in preparation at Wormley.
2. By pumping from the *Thames* through separate mains, for street and other such uses, or
3. By store of floods in Lea, or Thames, will be over and above the aforesaid 35,000,000 gallons.

I remain, &c.
James Muir.

William Pole, Esq., F.R.S.

APPENDIX BG.

Extracts from Report on the Chemical Quality of the Supply of Water to the Metropolis, by A. W. Hofmann, Professor of Chemistry in the Metropolitan School of Science, and Chemist to the Museum of Practical Geology, F.R.S., Ph.D., LL.D., &c., and Lindsey Blyth, Esq., Lecturer on Natural Philosophy at St. Mary's Hospital.

(This Report was made in 1856 to the Right Hon. William Cowper, M.P., President of the General Board of Health, together with an Engineering Report on the Works of the Companies, as altered under the provision of the Metropolis Water Act, 1852.)

The object of the inquiry being to obtain a view of the value of the waters in a sanitary respect and for domestic purposes, it was thought advisable to exclude from the investigation all details which did not directly affect this question.

In accordance with your instructions we have therefore confined ourselves in the analyses to:—

I. The determination of the hardness of the waters, *a.*, before boiling (permanent plus temporary hardness), and *b.*, after boiling (permanent hardness).

II. The determination of the total amount of solid matter contained in the waters.

III. The determination of the organic matter contained in the waters.

It was, moreover, considered important to repeat these determinations from time to time, so as to obtain some insight into the variations of the waters during the several seasons.

Of the above three determinations, the examination of the organic matter which is present in waters is of an especial interest in a sanitary point of view. This examination is attended with very considerable difficulties. The accurate determination of the quantity of organic matter in a water is one of the most delicate operations in analytical chemistry. Still greater is the difficulty of examining into

the nature of the organic matter; the total amount of organic matter is so small that immense quantities of water must be evaporated in order to obtain the material upon which to work, and few indeed are the data upon which a satisfactory examination of this kind can be founded at the present moment.

Very little is known of the nature of the ill-defined substances which constitute the organic matter generally found in water. Berzelius distinguishes two substances, crenic and apocrenic acids, which slightly differ in their chemical deportment; but these two bodies are as yet scarcely chemically examined, and much doubt still hangs over their individuality and even over their existence. The organic matter in water has been divided into *nitrogenous* and *non-nitrogenous* matter; but all we know is, that certain varieties of the organic matter found in water contain nitrogen, which is readily shown by treating them with hydrate of potash, when abundance of ammonia is evolved.

The opinions of chemists are divided as to the manner in which organic matter in water is capable, under certain conditions, of producing a deleterious effect upon the animal economy. But it is now generally admitted, that the substances which constitute the organic matter of water act injuriously by no means in consequence of being poisonous themselves, but by undergoing those great processes of transformation, called decay and putrefaction, to which all vegetable and animal matter is subject, when no longer under the control of vitality, either in plants or animals. These putrefactive processes either give rise to the formation of poisonous bodies, or they act simply as ferments, generating similar processes of decomposition in the substances composing the animal organism. Now, with special reference to the last mode of action, it is well established by general experience that *nitrogenous* substances are infinitely more liable to undergo putrefaction than organic bodies from which nitrogen is absent. And hence the very general and correct opinion that the deleterious character of organic matter in water is proportionate to the amount of *nitrogen* which it contains. Could this nitrogen be estimated with any degree of accuracy, such an estimate would certainly afford the most satisfactory element in the examination of the organic matter. Unfortunately this estimate is attended with very considerable difficulties. The nitrogen of the organic matter which has undergone putrefaction, and has therefore ceased to be deleterious, remains in the water, partly as ammonia, partly as nitric acid. It would therefore by no means be sufficient to evaporate the water and to determine the amount of nitrogen in the residue. It would be absolutely necessary to estimate also the nitrogen present in the form of nitric acid and of ammonia, and only after the deduction of their joint amount from the total amount, numbers would be obtained, which, representing the quantity of still putrescible nitrogenous substances, would afford, within certain limits, the necessary data for a comparison of the organic matter present in different waters.

It is obvious that this mode of proceeding is very complicated, and not likely to furnish trustworthy results, unless carried out with the greatest circumspection, and with all the appliances which the modern progress of analytical chemistry can suggest. It was our intention to enter fully into this part of the inquiry, and a series of experiments were actually made by us with the view of fixing on the best method of conducting the inquiry. The illness of Mr. Blyth, which at this period deprived us of his assistance, has compelled us to abandon, for the present at least, this part of the examinations, and to confine ourselves to an accurate determination of the hardness (permanent and temporary), of the total amount of solid constituents, and of the organic matter.

Collection of the Waters.

* * * *

The first series of samples were taken at your desire from the mains of each company, as near as possible to the houses supplied, so as to insure a fair estimate of the actual quality of the water used by the inhabitants of the metropolis.

* * * *

The exact source of each sample, and the date of taking it, are stated in the tables giving the result of the examination.

In the second series of samples, taken at a later period of the year, it was desired to obtain some information as to the effects of filtration. To this end, samples were taken of the waters before and after filtration at the works of each company, and with the co-operation of their officers, as well as from the mains within the district supplied. As in the first instance, the source of the waters and the date of taking them are stated in the tables.

* * * *

Chemical Examination of the Water.

The following tables exhibit the results obtained in the analysis of the ten waters submitted to examination. It may be stated that each number contained in the table is, with one or two exceptions, the mean of two well concordant experiments, the details of which are united in the Appendix. The hardness was determined by the well-known elegant process of Professor Clark; the second determination (of the permanent hardness) being made after five minutes boiling. This deserves particularly to be mentioned, inasmuch as by protracted ebullition the hardness may be still further reduced. The total amount of solid constituents was determined by evaporating an exactly measured quantity of the water with a known amount of carbonate of soda in platinum capsules, and weighing the residue, dried at a temperature of 248° F., in the same capsules. This residue ignited, and subsequently moistened repeatedly with solution of carbonate of ammonia (to replace the carbonic acid which lime and magnesia salts might have lost during the ignition), and dried at a gentle heat until the weight had become constant, furnished the amount of saline, and, by calculation, the amount of organic matter.

For the sake of comparison we have added in each case the results obtained, in 1851, by the Government Commission (consisting of Professors Graham, Miller, and Hofmann).

I.—Water supplied to the Metropolis by the Grand Junction Water Company.

Results obtained in 1856.

Description of Water.	Date of taking.	Hardness.			Solid Constituents, Grains per Gallon.		
		Total.	Permanent.	Temporary.	Total Solid Residue.	Organic Matter	Inorganic Matter
From main in Grand Junction Road; filtered.	Jan. 18	15·95	9·05	6·90	23·35	1·98	21·37
From stand pipe in Piccadilly; filtered.	Mar. 29	14·10	6·50	7·60	21·21	1·015	20·195
From pipe at works coming from Hampton; unfiltered.	Mar. 29	14·55	8·2	6·35	23·22	1·17	22·05

Results obtained by the Government Commission in 1851.

Nearest accessible point to the works of the Company.	Between Jan. 29 and 31.	14·00	—	—	21·72	3·07	18·65

II.—Water supplied to the Metropolis by the West Middlesex Water Company.

Results obtained in 1856.

Description of Water.	Date of taking.	Hardness.			Solid Constituents, Grains per Gallon.		
		Total.	Permanent.	Temporary.	Total Solid Residue.	Organic Matter	Inorganic Matter
Service pipe near Dorset Square; filtered.	Jan. 18	13·65	9·4	4·25	21·16	0·819	20·341
From cab-stand, Broadway, Hammersmith; filtered.	Mar. 31	14·4	7·4	7·0	19·897	1·015	18·882
From Hampton; unfiltered.	Mar. 31	14·8	7·55	7·25	22·05	1·05	21·00

Results obtained by the Government Commission in 1851.

VIII.—Water supplied to the Metropolis by the Kent Water Company.

Results obtained in 1856.

Description of Water.	Date of taking.	Hardness.			Solid Constituents, Grains per Gallon.		
		Total.	Permanent.	Temporary.	Total Solid Residue.	Organic Matter	Inorganic Matter
From service pipe, New Cross; filtered.	Jan. 23	12·45	12·3	0·15	28·49	1·26	27·23
From well at works, as being pumped into mains; filtered.	April 5	11·1	9·3	1·8	23·87	1·19	22·68
From subsiding reservoir, at works, Deptford; unfiltered.	April 5	12·55	8·70	3·85	27·30	1·382	25·918

Results obtained by the Government Commission in 1851.

Nearest accessible point to the works of the Company.	Between Jan. 29 and 31.	16·0	—	—	29·71	2·61	27·10

IX.—Water supplied to the Metropolis by the Hampstead Water Company.

Results obtained in 1856.

Description of Water.	Date of taking.	Hardness.			Solid Constituents, Grains per Gallon.		
		Total.	Permanent.	Temporary.	Total Solid Residue.	Organic Matter	Inorganic Matter
From service pipe at cottages, Highgate Hill; mixed.	Jan. 22	10·5	10·5	0·0	34·26	1·29	32·97
From service pipe; mixed.	April 4	5·45	5·40	0·05	30·765	1·47	29·295
From well at Hampstead; unfiltered.	April 4	4·7	3·9	0·8	57·101	2·24	54·861
From the works at Highgate; unfiltered.	April 4	6·35	6·35	0·0	22·54	1·575	20·965

Results obtained by the Government Commission in 1851.

Nearest accessible point to the works of the Company.	Between Jan. 29 and 31.	9·8	—	—	35·41	1·81	33·57

X.—Water supplied to Woolwich by the Woolwich and Plumstead Water Company.

Results obtained in 1856.

Description of Water.	Date of taking.	Hardness.			Solid Constituents, Grains per Gallon.		
		Total.	Permanent.	Temporary.	Total Solid Residue.	Organic Matter	Inorganic Matter
From works at Plumstead; softened.	Jan. 25	8·15	8·1	0·05	18·84	0·75	18·09
From service tap at the cottages near the railway station, Woolwich Arsenal.	April 5	12·85	10·05	2·80	21 85	1·015	23·835
From well at works; unsoftened.	April 5	22·65	10·25	12·40	33·163	1·05	32·113

The analytical results tabulated in the preceding pages demand but little interpretation. The number of analytical determinations, although considerable, is not sufficient to furnish the data which are necessary for the elaboration of a definite view regarding the fluctuations in the composition of the waters supplied to the metropolis at different seasons. In fact, the elements which are capable of influencing the composition of the waters are so manifold and liable to such extraordinary variations, that it becomes obvious that the number of estimations has still to be considerably increased. Then only will it be possible to eliminate the influence of accidental disturbances upon the general features of the analysis. It would therefore be premature to enter into a comparative discussion of the results obtained in January and in April, and of the slight discrepancies exhibited by the analyses of the waters of the same company taken at different localities and under circumstances otherwise different.

A most interesting fact, however, is elicited, if the average result obtained in 1856 be compared with the results of the analyses made in 1851 by the Government Commission.

In the following table these results are placed in juxtaposition:—

Comparison of the Average Results obtained in the Analysis of 1856 *with those of the Analysis made in* 1851.

Description of Water.	Date of taking.	Hardness.			Solid Constituents, Grains per Gallon.		
		Total.	Permanent.	Temporary.	Total Solid Residue.	Organic Matter	Inorganic Matter

	1856	12·03	10·1	1·93	26·10	1·37	24·73
Hampstead Water Company.	1851	9·8	—	—	35·41	1·84	33·57
	1856	7·43	7·41	0·02	29·19	1·45	27·74

This table shows that the hardness of the waters in 1856 was, with one exception, somewhat less than in 1851; the diminution, however, with one or two exceptions, is only trifling. The total amount of solid matter in the two years likewise exhibits but unimportant fluctuations.

A very considerable diminution, however, is observed in the amount of organic matter.

In fact, in 1856 the waters supplied to the metropolis contained not more than one-half of the organic matter which was present in the year 1851.

This result is certainly not accidental. The diminution is not merely an average result, but uniformly observed throughout. The waters examined in 1851 were taken in January; those investigated in 1856, partly in January and partly in April. The diminution of the organic matter cannot therefore be due to the influence of the season. Nor can it be due to any difference in the mode of determining the organic matter in 1851 and 1856. These determinations were made by exactly the same method; for it so happens that the analytical part of the inquiry in 1851 which refers to the organic matter was likewise made in the laboratory of the Royal College of Chemistry. The diminution is obviously partly due to the alteration of the localities from which many of the companies derive their supply. The Grand Junction, the West Middlesex, the Southwark and Vauxhall companies, formerly supplied respectively at Kew, Barnes, and Battersea, derive their present water from Hampton; the Lambeth Water Company used to take their water at Lambeth, but have now erected extensive works at Thames Ditton. The diminution of the organic matter in the London water supply is, however, by no means confined to the companies that have changed the locality of their source, and it must therefore be attributed in a great degree to the considerable improvement which has taken place in the collection, filtration and general management of the supply of water to the metropolis.

APPENDIX BJ.

INFORMATION from Mr. TAUNTON as to GAUGINGS of the THAMES at LECHLADE, and other data affecting the Upper Basin of the Thames.

Brimscombe Port, Stroud,
January 30, 1869.

DEAR SIR,

IN reply to yours of the 21st instant, I have now the pleasure to send you enclosures marked A, the gaugings of the Thames at St. John's Lock, as made by me in October and November 1867, during a short-water period. I append copy of the Rain Gauge Returns (enclosure marked B) kept at Thames Head from 1859 to 1869, and you will observe that whilst the average quantity of rain that fell within that period has been for October 2·77 inches, and November 2·19 inches, it was in 1867 1·99 inches for October, and ·98 inches for November. You will notice also that the rainfall at Thames Head of 1867 was about two inches below the average. The gaugings were therefore taken at a proper period, which I selected when I had the means of putting stop planks across the head of the lock at St. John's, Lechlade, and you may depend upon them.

I send enclosure marked C, a return as to the summit level of the Thames and Severn Canal from 1863 to 1865, both inclusive (which was prepared for a Parliamentary inquiry in 866), that may be of service to your Commission. It gives the quantity of water pumped weekly at Thames Head into the navigation and the lockage, eastwards and westwards, that is, towards the Thames and the Severn respectively.

I also forward enclosure marked D, a section along the Stroud water and Thames and Severn Canal between these two rivers. (See Appendix B K.)

In reference to the Cotteswold district, the large volume of the springs with which it abounds, such as those at Bibury, Syreford, Foss Bridge, South Cerney, Chalford Thames Head, &c., yielding some of them as much as 3,000,000 gallons each per diem, quite characterizes that district, and distinguishes it from those localities where the waters mainly pass off down surface channels, and where reservoirs must be formed for the storeage and utilization of such waters.

Here the storeage is already effected by nature in subterranean reservoirs, being the cavities in the loose rocks of the inferior or great oolites, into which the rain so freely permeates that floods and surface torrents are here unknown. The bottom of these reservoirs in the inferior oolite is the upper lias clays, and in the great oolite the fuller's earth bed forms the impervious floor.

The springs to which I have referred are outlets from these reservoirs.

But it happens that the spring waters, after coming to the surface, are sometimes lost again in the loose ground traversed by their surface channels, and that much water due to the valley of the Thames is lost from it.

First. My idea is to get back this or some large portion of it.

Secondly. That if a supplemental supply brought from a long distance is required for London, a separate service of the purest spring water sufficient for the whole of the inhabitants of London for drinking and culinary purposes may be obtained from the Cotteswolds, and conveyed throughout in covered conduits.

Thirdly. The waterclosets being the great consumers of water, it seems to me there are adequate sources of supply for them, as well as for domestic, manufacturing, and general purposes at present.

I have repeated these remarks, contained in mine to you of the 13th March 1868, as I have not had the opportunity of giving them in evidence before your Commission.

Believe me, yours faithfully,
JOHN H. TAUNTON.

W. Pole, Esq.

ENCLOSURE A.—A TABLE of the GAUGINGS of the THAMES at LECHLADE, St. John's Lock, by Overfall 15 feet wide, and of RAINFALL at BRIMSCOMBE and THAMES HEAD, during October and November 1867.

APPENDIX BL.

LETTERS on the DEFICIENT SUPPLY of WATER in case of FIRE in the BOROUGH of SOUTHWARK.

St. Saviour's District Board of Works,
Board Room, Emerson Street,
Bankside, Southwark, S.E.

DEAR SIR, Water Supply. December 11, 1868.

I AM directed by the St. Saviour's District Board of Works to forward to you, for your information, copies of a letter or memorial to the Board from hop factors having premises in the vicinity of the Borough, complaining of the inadequate supply of water, and of the letter of the Southwark and Vauxhall Water Company in reply thereto.

The Board have directed the forwarding of the same to you, thinking perhaps that you might deem it expedient to submit the same to the Committee on the Water Supply, of which you are a member.

I am, &c.

Sir John Thwaites. HERBERT STURMY, Clerk.

The St. Saviour's District Board of Works.

GENTLEMEN, Borough, October 27, 1868.

WE beg to draw your attention to the fact that the premiums of insurance from fire have since last Michaelmas been advanced 75 per cent. on all hop warehouses in the Borough, on the ground (as stated in the various renewal notices) of the wholly inadequate supply of water.

The manager of one of the leading city fire offices writes thus:—"The recent advance in the rate of premium for hop "warehouses in the Borough was only made after the "subject had been fully discussed by the associated offices, "and as *the water supply throughout the whole district is so "scanty as to be ineffectual for the prompt suppression of "any large fire, it was resolved,*" &c.

The manager of another writes thus:—

"It" (the advance) "is adopted by all the companies, "and would not have occurred but from the fact recently "ascertained of the *very inefficient supply of water in your "district when a fire arises.* The cause has been fully re- "ported on by competent persons, and the offices are "satisfied that unless the owners of property interested "agitate the question of the better means of supplying "water, they must protect themselves by asking such rates "as they think are adequate to the risk."

If this be the case *all* property in this district must be in at least equal danger should a fire break out, and it may spread widely if the supply of water is inadequate to extinguish it. We trust you will inquire into the subject, and if those statements be correct exercise your powers to make the water companies supply sufficient water for the protection of the property of your ratepayers.

Yours obediently,

T. PARKES & SON, 7, Counter Street.
S. H. MOUNTAIN, Red Cross Street, Boro'.
P. S. PUNNEK, for the Hop Planters' Company, Southwark Street.
EVANS & CO., 227, High Street.
WM. DUNK & SONS, 230, High Street.
WOOLOTON & SON, 246, High Street.
PATTENDEN & SMITH, 14, Southwark Street.
J. T. NOAKES, 4, Southwark Street.
W. COSIER & CO., 15, Three Crown Square, Boro'.
THOS. RICHARDSON & SON, 6, Duke Street, Southwark.

Southwark and Vauxhall Water Company,
Sumner Street, Southwark,

DEAR SIR, November 28, 1868.

I BEG to acknowledge the receipt of your letter of the 17th instant, enclosing copy of a memorial sent to the St. Saviour's Board of Works on the subject of short supply of water in case of fire to the hop warehouses, &c. in the Borough and its vicinity.

In reply, I am instructed to inform you that the short supply referred to arises from no fault of this company, but solely in consequence of the owners of the hop and other warehouses making no provision themselves to insure a proper supply. The company's pipes are laid throughout the district of sizes proportioned to the demand for water by their servants, and unless special fire-mains are laid by the owners of property, the supply of water for fire purposes can only be procured from the ordinary street service pipe, excepting in those where a leading main may happen to be laid.

So far as the company is concerned, it is evident that they could not afford an additional expenditure for fire-mains for which they would receive no remuneration whatever, as the supply of water for fires is in all cases afforded gratuitously. The company already loses heavily in consequence of many of the hop and other warehouses being built on sites formerly occupied by numbers of small houses, to supply which the pipes were originally laid, and for which a considerable revenue was receivable, whereas the supply taken at the hop warehouses seldom exceeds the quantity required for washing hands, &c., at a rate of from 21*s.* to 42*s.* per annum. In many cases no water whatever is laid on to the hop warehouses, and therefore no rate paid.

The company have always been desirous to assist by every means in their power the owners of property in making provisions against fire, and have offered, and still offer, to allow any fire-mains that may be laid to be connected with their leading mains, without any charge or rate whatever, but the owners of property have in very few instances availed themselves of this privilege.

I am, &c.
CHAS. ROBINSON, Secretary.

To Herbert Sturmy, Esq.,
St. Saviour's District Board of Works,
Emerson Street, Bankside, Southwark.

APPENDIX BM.

LETTERS from Mr. HASSARD and Mr. SYMONS, on the RAINFALL in the LAKE DISTRICT during the Drought of 1868.

1, Westminster Chambers, Victoria Street, S.W.,
December 15, 1868.

DEAR SIR,

IN order to set at rest the question of how far the drought of last summer would have affected our project for supplying the metropolis, &c. with water from the Lake district, I have, since receiving your last communication, applied to Mr. Symons to let me know what amount of rain fell there during the drought in other parts of the country.

You will see from his letter, which I enclose, that the average rainfall in that part of the Lake district constituting our gathering ground, was, for the months of April, May, June, July, and August, 23·09 inches, and, further, that our reservoirs would have been quite full at the commencement of the drought.

All the stations, excepting Seathwaite, in the table of rainfall given by Mr. Symons are within our collecting area, and in the average at foot of the table you will see that Seathwaite has been excluded.

Out of the 23·09 inches of rain which fell in the Lake district during the drought elsewhere, there would, from the steep and non-absorbent nature of the ground, have flowed into the reservoirs at least 15 inches; this quantity from the area of our gathering ground would amount to 154 days' supply of 250,000,000 gallons, so that during even this period of drought the supply would have rather

exceeded the demand, so far as regards towns supply, leaving the compensation water only, or about 80,000,000 gallons daily, to be drawn out of the reservoirs. The sufficiency of our project in this respect is therefore placed beyond dispute or doubt.

Will you have the kindness to lay this communication and Mr. Symons' letter accompanying it before the next meeting of the Commission, and oblige

Yours faithfully,

W. Pole, Esq., C.E., F.R.S. RICHD. HASSARD.

62, Camden Square, London, N.W.,

December 15, 1868.

DEAR SIR,

I HAVE not hitherto had time to go critically into the late drought, nor can I do so for a month at least, but assuming the question to resolve itself into the simple form of—Was there any available rainfall during the months of April, May, June, July, and August? I reply that at most of the Lake stations the fall amounted to between 20 and 30 inches, that is to say, that the fall in those months was more than the average fall in a whole year in the midland and eastern counties.

May, June, and July were dry, especially the latter, but the figures overleaf will show you that a drought in the Lake district is very different from a drought anywhere else.

I need not tell you that in the Cumberland district the winter rains are even more important than elsewhere, and as the drought followed three months in which there had been *between* 30 *and* 40 *inches*, it is obvious that your reservoirs would have been full to overflowing when it set in.

I add a column giving the total fall in eleven months of this dry year.

Yours very truly,

R. Hassard, Esq., C.E. G. J. SYMONS, F.M.S.

Ammonia in water (*see* Quality of Water).

Ampney, springs at, *Bravender*, 6906; App. O, AX.

Amwell, springs and well at, *Clutterbuck*, 1836; *Muir*, 3969, 4002–7; App. O, AX.
—— analysis of, *Muir*, 4077.

Analysis of waters, on modes and processes of, *Wanklyn*, 5418–97; *Odling*, 6482–4; *Brodie*, 6996–7003; *Miller*, 7104–16.
—— difficulty of, as regards organic matter, **181.**
—— of Lake waters, *Way*, 1454–83.
(*See* Quality. Lake Project.)
—— of Welsh waters (*see* Quality. Welsh Project).
—— of springs (*see* Springs.)

Analyses of London and Thames waters, **152–3, 182.**
By Commission of 1828, **104.**
Commission of 1851, **110, 159, 163, 167, 171, 182**; App. AH.
Hoffman and Blyth, 1856, **113, 182**; App. BG.
Letheby, Odling, and Abel, 1867, **159**; App. AG.
Do., do., 1868, **159**; App. AH.
Frankland and Odling, 1868, **186**; App. AX, BE.
Campbell, *Beardmore*, 3323–5.
Registrar General, **194**; App. AJ; *Farr*, 2847–62.
Wanklyn, 5431; App. AK.
(*See also* Quality of Water.)

Area of Thames basin, **84.**
—— of district supplied by each London water company, **124.**
—— of gathering ground for Welsh project, **12**; *Bateman*, 25–6, 6701–2.
—— of gathering ground for Lake project, **44**; *Hemans*, 319.

Ashton, water supply of, *Bateman*, 277, 6488.

B.

Bain, Alexander, his evidence, 3797–3858.

Bagshot Sands, and the water from them, **78, 80–87**; *Hennell*, 1922, 1929, 2038–9; App. O, AX.
—— in connexion with M'Neill's scheme for supplying London, **80**; *Macneill*, 5817–5958.

Bala Lake, nature of district and water from it, **49**; *Bateman*, 59, 137; *Hassard*, 589–604, 854, 883–98; *Rawlinson*, 1381–1423; *Ramsay*, 1743–8; *Whalley*, 2076–7; *Hawksley*, 2569–72, 2580; *Simpson*, 4620; App. C, D.

Bateman, J. F., his evidence, 1–286, 6485–6748, 7404–7443; App. M.
—— quoted, **23, 39, 60, 135, 164, 168, 172, 221, 225, 240, 247, 253, 254.**
—— pamphlet descriptive of his Welsh project, App. E.
—— essay on constant service, App. I.
—— gaugings of the Thames, *Leach*, 4306–8.

Barbadoes, water in, *Parkes*, 3241.

Barlow, P. W., his evidence, 5959–81.
—— quoted, **74.**

Barnsley, water supply of, *Hawksley*, 7528.

Barton Spring, *Clutterbuck*, 1884.

Basingstoke Canal, proposed supply from, **78**; *Hennell*, 1920–2040.

Banbury, water supply of, App. AJ.

Barrow, River, App. BD.

Beardmore, N., his evidence, 3255–3445, 7444–57.
—— quoted, **136, 140, 142, 143, 164, 185, 225, 240.**

Béchamp, his experiments, *Frankland*, 6334.

Bed of the Thames, changes in the, *Burstal*, 3620–7.

Beddington sewage farm, App. O.

Bedhampton, springs at, *Ewens*, 3693–3703.

Belgravia, water supply in, *Simpson*, 4627–9.

Bermuda, water in, *Parkes*, 3240; *Remington*, 4432–3.

Bibury Spring, *Bravender*, 6906.

Bill for amalgamation of London water companies, 1851, **111.**

Birkenhead, water supply of, *Duncan*, 2328; App. AM.

Birmingham, water supply of, *Bateman*, 269–72; *Hassard*, 852–3; *McClean*, 5690–3, 5734–5; App. AG.

Blackburn, water supply of, *Bateman*, 277–9, 6488.
—— drought at, *Bateman*, 7412–5.

Blackwater River, App. O.

Blackwell, quoted, **140.**

Blyth, analysis by. (*See* Hoffman.)

Board of Health, opinions on the water supply of London, quoted, **109, 150, 160, 163, 166, 170, 205, 237**; *Bateman*, 59–62; *Bain*, 3798–3858.

Boilers, kitchen, incrustations in, **169**; *Miller*, 7124–6.

Bolton, water supply of, *Bateman*, 6488; App. BC.
—— reservoir, *Bateman*, 48.

Boussingault's experiments, **194**; *Frankland*, 6324.

Boston, water supply of, *Simpson*, 4700.

Boxwell Spring, App. O.
(*See also* evidence of *Brown* and *Bravender.*)

Bradford, water supply of, App. AM.
—— drought at, **60**; App. BC.
—— springs at, *Harrison*, 3024.

Brande, Professor, **104.**

Bravender, John, his evidence, 6888–6915.
—— his proposal for water supply to London, **70, 81.**
—— memorandum on Upper Thames basin, App. H.

Brewing, hard and soft water for, *Way*, 1499*a*–1503; *Hawksley*, 2514; *Frankland*, 6360.

Bridgnorth, water supply of, *Bateman*, 273.

Bridgwater Canal, *Rawlinson*, 1331–3.

Brighton, water supply of, *Barlow*, 5964; *Homersham*, 6824–6833.

Bristol, water supply of, App. AM.
—— insufficiency of supply, **58**; App. BB, BC.

Brodie, Sir B., his evidence, 6979–7044.
—— quoted, **164, 184, 201.**
Bromley, well at, *Morris*, 6108.
Brown, T. C., his evidence, 6838–50.
—— quoted, **69–81.**
Burnley, water supply of, *Bateman*, 6488.
Burstal, Capt., his evidence, 3572–3684, 6851–62.
—— quoted, **140, 198–200.**
Bury, water supply of, *Bateman*, 277, 6488.
—— drought at, **60**; App. BC.

C.

Cambridge, water supply of, *Beardmore*, 3351–3; App. I.
Campbell, his analyses of various waters, *McClean*, 5556; *Homersham*, 6796–6809; *Meeson*, 6878.
Canal, Basingstoke. (*See* Basingstoke Canal.)
—— Thames and Severn, *Denton*, 1658–61, App. BJ, BK.
Canterbury, water supply of, App. AG.
Capital of London water companies, **124.**
Carlisle, water supply of, App. AJ.
—— sewage treatment at, *Burstal*, 6853.
Castle Howard, water supply of, *Homersham*, 6793–6803.
Catchment basins of rivers in England and Wales, **3, 252**; App. BN.
Catchwater drains in Lake district, *Hassard*, 711–2.
Caterham, water supply of, **75**; *Wanklyn*, 5431; *Homersham*, 6793–837; App. O, AX.
Caversham Bridge, Thames at, App. O, AX.
Chalk, water supply from the, **73–77, 88, 145–7**; *Hawksley*, 2520; *Harrison*, 3048–58; *Clutterbuck*, 1785–1893; *Beardmore*, 3272–80; *Bain*, 3799–858; *Barlow* 5960–81; *Homersham*, 6821–37; App. O, AF, AX. (*See also* Muir's evidence.)
Charing Cross Well, **123.**
Chapman's mode of analysis. (*See* Wanklyn's evidence.)
Chatham, water at, *Parkes*, 3136, 3201–8.
Chelsea Waterworks Company, description and statistics, **98, 105, 117, 123, 124**; *Simpson*, 4599; App. P.
—— future means and prospects, **231**, App. L.
Cheltenham, water supply of, *Bravender*, 6901.
Cherbourg, iron pipes at, **174**; *Rawlinson*, 1906; *Playfair*, 2680.
Cherwell River, App. O, AX.
Cheshunt, well at, *Muir*, 3984.
Chester, water supply of, *Duncan*, 2328; App. I., AM.
Chiltern Hundreds Waterworks, Homersham, 6799–6809.
Chadwell and Amwell Springs, **97.**
Cholera, communication of, by water, **215**; *Parkes*, 3121–3, 3169–76, 3192–4; *Letheby*, 3898–911. (*See also* Germs of Disease.)
—— in London, **127, 205**; *Simon*, 2755–64, 2820; *Farr*, 2865–82; *Beardmore*, 3388–96; *Letheby*, 3901–8; *Orton*, 4172–239; *Simpson*, 4628–37; *Frankland*, 6252–8.
—— in Liverpool, *Duncan*, 2317–21.
—— in Southampton, *Parkes*, 3162.
Chorley, iron pipes at, **174.**
Churn, River, *Denton*, 1663–4; *Clutterbuck*, 1881–2; *Brown*, 6840–1; *Bravender*, 6901.
City of London, water supply to, *Simon*, 2741–4.
Cirencester, rainfall at, **69**; *Brown*, 6838–42.
—— drainage of, App. O.
Cisterns, house, retained under constant service, **238.**
Claremont, lead in water at, *Simpson*, 4757.
Clark, Dr., on the hardness of water, and on his softening process, **75, 158, 173, 175–6**; *Homersham*, 6762–6837; App. G.
Classification of waters, *Parkes*, 3147–51.
Clay, London, **87.**
—— Weald, **90.**
Clutterbuck, Rev. J. C., his evidence, 1782–1893.
—— quoted, **14, 74, 140, 185.**
Clyde, River, organic matter in, *Smith*, 7188–95.
Coal Measures, pipes laid over, *Duncan*, 2342–3.
Colne, River, Gloucestershire, *Bravender*, 6901.
—— Hertfordshire, **73**; *Hawksley*, 2520; App. O, AX, AY, BE.
Commission, Royal, of 1828, **104, 150, 182.**
—— Royal Chemical, of 1851, **73, 110, 150, 152, 159, 161–2, 167, 171, 174–5, 182, 195**; *Bain*, 3809–38; *Letheby*, 3939, App. AF.
—— Royal, on Drainage of London, 1857, **221.**
—— —— on Rivers Pollution, **126, 142–3, 150, 196, 204.**
Committee, Commons, of 1821, **103.**
—— of 1834, **106.**
—— of 1850–1–2, 110, 238.
—— of 1867, **127, 128, 206, 239, 242, 244.**
Companies, London Water, districts and works, **114–125**; App. AV.
—— provisions and prospects for the future, **230–2.**
Comparison of cost between Welsh and Lake projects, *Hassard*, 1059–60. (*See also* Bateman's evidence.)
Compensation to rivers, streams, and mills, **13**; *Bateman*, 36, 73, 113–5; *Whalley*, 2043; *Duncan*, 2127–37, 2306–16.
Competition between London water companies, **114.**
Conduits, ancient, in London, **95.**
Conduit, for Welsh project, **7, 39, 53**; *Bateman*, 101–2, 146–58, 215–37; *Rawlinson*, 1327–34; *Duncan*, 2411–28; *Hawksley*, 2527, 2534–48; *Parkes*, 3189; *Beardmore*, 3304–11; *Hassard*, 6934–63; App. E, AQ, AR.
—— for Lake project, **47**; *Bateman*, 158–75; *Hemans*, 301–3, 428–33; *Hassard*, 730–57, 765–7, 778–95, 800–17, 823–38, 6934–63.
—— for Dale's project, *Dale*, 1206–68, 1277–9.
—— for Wye project, *Fulton*, 3502–4; 3519–30; 3543–71; 4108–26; 4148–55.
Conservancy of the Thames and the Lee, **126–9, 196–202, 207, 216–7, 248**; *Beardmore*, 3331–43; *Letheby*, 3889–91; *Simpson*, 4586–93, 4638–9, 4652–70, 4733; *Hawksley*, 5074–5, 5097; *McClean*, 5676–82; *Frankland*, 6375–9; *Bateman*, 6607–10. (*See* Evidence of Thorpe, Burstal, and Leach.)
Constant service, system of supply, **128, 228, 233–43, 248, 262**; *Dale*, 1098–1119; *Hawksley*, 2529, 2557–63; *Playfair*, 2720–4; *Simon*, 2745–50, 2767–76, 2827–33, 2843; *Harrison*, 3072–6; *Parkes*, 3162–8; *Beardmore*, 3346–80; *Letheby*, 3912–8; *Muir*, 4054–76; *Orton*, 4211–8; *Simpson*, 4622, 4698–4706; *Holmes*, 4845–98, 4916; *Greaves*, 5155–67, 5202–10; *McClean*, 5587–5636; *Quick*, 6011–56, 6070–93; *Morris*, 6150–60; *Frankland*, 6269–70; *Bateman*, 6589–6604; *Miller*, 7085–6, 7223–8; *Heron*, 7386–90; App. I, AJ.
Contamination of Thames within the tideway, **107.**
—— organic, from Thames basin, **179.** (*See* Quality of Water.)
Control of water supply, **245–50, 263**; *Bateman*, 258–60; *Duncan*, 2429–33; *Hawksley*, 2528–33, 2566–6; *Holmes*, 4899, 4906–26; *Jackson*, 4967–70; *McClean*, 5575–86. (*See also* Heron's evidence.)
Copenhagen, water supply of, *Hawksley*, 2547.
Coral Rag, **91.**
Cockermouth, water supply of; App. AJ.
Coventry, water supply of, *Bateman*, 274.
Cray River, Barlow, 5979–81.
Crossness, well at, *Barlow*, 5978.
Croydon, well and water supply at, *Homersham*, 6833; App. O, AG, AM, AX.
—— sewage irrigation at, **202**, *Simpson*; 4639, 4663–8; *Frankland*, 6378–9; *Burstal*, 6853; App. O, AX.
Culinary purposes, effects of hardness for, **166–9.** (*See* Hard and Soft Water.)
Cultivation in Thames basin, *Parkes*, 3177–88.
—— in Welsh district, **20**; *Hassard*, 979–1025; *Ramsay*, 1781; *Whalley*, 2094–5; App. B.
Cumberland Lakes (*see* Lake Project).

D.

Dale, Thos., his evidence, 1061–1305.
—— quoted, **225, 240.**
—— his project for London water supply, **57**; *Dale*, 1064–1305; App. Q.
Darenth or *Dart*, River, *Barlow*, 5979–81.
Delify Mines, Hassard, 1038, App. B.
Denton, Bailey, his evidence, 1529–1706.
—— quoted, **140.**
—— his project for supplying London, **68, 81**; *Denton*, 1532–1706; App. V.

Derby, water supply of, App. AG, AM.
Derbyshire, proposed supply of London from, **56**; *Remington*, 4324–4442.
Dewsbury, water supply of, *Bateman*, 6488.
Diarrhœa caused by impure water, *Parkes*, 3190.
Diseases communicable by water, **215**; *Parkes*, 3114–23. (*See* Cholera, Fever, Germs.)
Distribution of water in London, **125**; *Simpson*, 4741–3.
—— proposed under Welsh project, **9**; *Beardmore*, 3440–5; *Simpson*, 4618–2; *Bateman*, 6570–4.
Don, River, self purification of, *Hawksley*, 5076.
Dorking, analysis of water at, *Wanklyn*, 5431.
Double Supply in London, *Harrison*, 3110; *Leach*, 4318–20.
Dove, River, proposed supply from, **56**; *Remington*, 4324–4442.
Dover, water supply of, App. AG.
Drainage, land, as affecting water supply, *Denton*, 1529, 1549–54.
—— on the Lee, *Greaves*, 5188–93.
—— area for Lake and Welsh projects. (*See* Area.)
Draught, unequal, of water at various parts of the day, **235**.
Drifts in the chalk, *Harrison*, 3095–3100. (*See* Chalk.)
Drinking, effects of hardness for, **163–5**. (*See also* Hard and Soft Water.)
Droughts in Lake district, *Symons*, 441.
—— of 1864–5; *Bateman*, 6515*a*.
—— of 1868, **59–64**; *Bateman*, 7404–7443; *Beardmore*, 7444–57; *Hawksley*, 7490–7537; App. BB, BC.
Dublin, water supply of, *Hassard*, 549–84, 757*a*; *Bateman*, 7408.
Dudley, water supply of, *Bateman*, 269.
Duncan, Thomas, his evidence, 2097–2454.
—— quoted, **39**, 164–172, **225**, **247**.
Dundee, water supply of, App. AG, AM.
Du Pasquier on dyeing, *Playfair*, 2707.
Durham, water supply of, App. AG.
Dwngwm Mine, *Hassard*, 1038; App. B.
Dyeing, comparison of soft and hard water for, **173**; *Way*, 1504; *Dale*, 1079–83; *Hawksley*, 2515; *Playfair*, 2705–7; *Hawksley*, 5109–12; *Frankland*, 6358–9. (*See* Frith's and Jubb's evidence.)
Dysentery, caused by impure water, *Parkes*, 3190.

E.

Eachus, G. E., his evidence, 2607–2633.
Eastbourne, water supply of, *McClean*, 5639–40; 5723–8.
East London Waterworks, description, statistics, &c., **102**, **105**, **116**, **123**, **124**, **142**; *Farr*, 2865–82; *Greaves*, 5123–5211; App. P.
—— constant service given by, *Beardmore*, 3349.
—— proposed supply from the Thames, and future prospects, **127**, **231**.
East London, cholera in, 1866. (*See* Cholera in London.)
Economy produced by municipal management, **248**.
Edinburgh, water supply of, App. AG, AJ, AM.
Embankment of the Upper Thames, **67**.
Enfield Chase, proposed reservoirs in, **72**. (*See* Mylne's evidence.)
Estimates for Welsh project, **25–27**, **32–35**; *Bateman* 207–37; *Hawksley*, 2529; *Simpson*, 4770–3; *Bateman*, 6564–88; *Hassard*, 7159–67; App. M.
—— for Lake project, **50**, **51**, **53**; *Hassard*, 812–7, 846–51, 1060, 7168–82.
—— for Wye project, *Fulton*, 4093–4107, 4118–22, 4142–7.
Evaporation and absorption, loss of rainfall by, *Bateman*, 28–36; *Hemans*, 325–40; *Symons*, 457–63; *Duncan*, 2121–6; *Hawksley*, 2480; *Harrison*, 2958–66, 3036–40; *Brown*, 6839–40; *Hawksley*, 7504–26.
Ewens, G. W., his evidence, 3685–3796
—— reference to his project, **79**, **81**.

F.

Farnham, action of soft water on iron pipes at, *Way*, 1494.
Farr, Dr., his evidence, 2844–2930.
—— quoted, **184**.
Fencing to conduit for Lake project; *Hassard*, 720–8.
Fever, communication of, **215**; *Simon*, 7127–41. (*See* Diseases, Germs.)
Filtration, **104**, **105**, **124**, **209–212**, **248**; *Simon*, 2795–6; *Parkes*, 3143–6; *Frankland*, 6389–96, 6418–25; App. AG., AT.
—— by oxide of iron, *Miller*, 7089; *Smith*, 7264–5.
—— cost of, *Hassard*, 934; *Bateman*, 6604–5; App. K.
—— necessary for Welsh waters; *Hassard*, 1031–2.
Financial arrangements for Welsh project, **28**; *Bateman*, 6575–88, 6604–57, 6738–48.
Fires, extinguishing, **248**; *Quick*, 6031–7, 6043; App. BL.
—— in Manchester; *Bateman*, 6595–6; *Heron*, 7349–53.
Firth, Jos., his evidence, 5212–5319.
—— quoted, **172**.
Fisheries on the Severn, **38**; *Bateman*, 74–98, 123–132; *Whalley*, 2043, 2053–7.
—— in the Lake district; *Hassard*, 653–5.
—— in Scotland; *Bateman*, 74–98.
Fittings, house, **235**; *Rawlinson*, 1912.
Fleet pond, *Hennell*, 2030–1.
Fleetwood, water supply of; *Bateman*, 277.
Floods, great; *Rawlinson*, 1440–1, 1452.
—— in the Thames, **140**; *Beardmore*, 3323–5; *Leach*, 4271–7; *Hawksley*, 5061–5.
—— in Wales and the Severn, *Bateman*, 36; *Hawksley*, 2463–4; *Bateman*, 6662–6.
Frankland, Dr., his evidence, 6191–6432.
—— quoted, **23**, **24**, **164**, **168**, **172**, **182**, **184**, **186**, **200–2**, **240**; *Burstal*, 6851–62.
—— his analyses and processes, **152–3**; *Wanklyn*, 5420–97; App. AJ. (*See* Registrar General; also evidence by Miller, Brodie, Angus Smith, Morris.)
Frankland and Odling, analysis of Welsh and Cumberland waters, **17**; App. D.
—— Analysis of waters from Thames basin, **159**, **186**; App. AX, BE.
Froxfield, spring at, **88**; *Clutterbuck*, 1837.
Frost, effect of, in New River, *Hawksley*, 2534; *Muir*, 3990–8.
—— in Loch Katrine, *Bateman*, 6671–9.
Frost, anticipated effect of, in conduits of Welsh and Lake projects, **39**; *Bateman*, 244–6; *Duncan*, 2412–7; *Hawksley*, 2527, 2534–48; *Simpson*, 4617–8, 4687–91; *Bateman*, 6669–79.
Forth, navigation of, *Bateman*, 284.
Fullers' earth, **92**.
Fulton, H. H., his evidence, 3446–3571; 4078–4171.
—— his project, **54**; App. AA.
Future influences on the waters of the Thames basin, **195–202**.

G.

Ganges Canal, *Hassard*, 744.
Gases, absorption of, by soft water, **176**.
Gathering ground for Welsh project, **6**, **12**, **18**, **20**; *Ramsay*, 1709–81.
—— for Lake project, **44–53**; *Hemans*, 306; *Hassard*, 755–7; *Ramsay*, 1722–6.
—— for Wye project, *Fulton*, 3449–53
Gaugings of River Thames. (*See* Volume of Water in the Thames.)
Geology of Thames basin, **83**; *Harrison*, 3041–67; *Bravender*, 6902; App. X, Y.
—— of Welsh district, App. B, BA.
—— of Lake district, App. A, AZ.
Germs of disease in water, *Parkes*, 3114–23, 3169–76; *Hawksley*, 5082; *Wanklyn*, 5451; *Frankland*, 6401–4, 6421; *Brodie*, 7032–42; *Simon*, 7137–9; *Smith*, 7209; App. D, AJ.
Gibraltar, water at, *Parkes*, 3200.
Glasgow, water supply of, **26**, **29**, **50**; *Bateman*, 16–18, 59, 64–71, 146–206, 244, 260, 284–6; *Hassard*, 901; *Letheby*, 3942; *Bateman*, 6485–7; App. E, I, AG, AJ, AM, AO, BB.
—— drought at, *Bateman*, 7409–12.
—— mortality at, *Farr*, 2896–2915.
Glenridding Leadworks. (*See* Lead Workings in Lake District.)
Graham, Professor, member of Commission of 1851, **110**.
Grand Junction Waterworks, general description and statistics, **101**, **105**, **119**, **123**, **124**; *Quick*, 5984–98; App. P.
—— future means and prospects, **231**; App. L.
Gravesend, springs at, **74**; *Barlow*, 5961–81.
Gravitation supplies generally, **58–64**; App. BB, BC.

Grays, Essex, waterworks and springs at, **74**, **123**; *Meeson*, 6863–87.
Great Western Railway, conveyance of water to London by, *Whalley*, 2066–75.
Greaves, Charles, his evidence, 5121–5211.
—— quoted, **140**, **143**, **201**, **225**, **240**.
Greensands, **89**, **147**.
Greenwich, rainfall at, **62**.
Grenelle, well at, *Odling*, 6475.
Grenoble, iron pipes at, **174**; *Way*, 1494; *Rawlinson*, 1906; *Playfair*, 2678.
Greta River, *Hemans*, 369; App. A.
Greywell, springs, *Hennell*, 1947.
Groups of provincial towns, supply of, **256**; *Holmes*, 4928–30; *McClean*, 5653–71, 5683–5.
Guildford, water supply of, App. AG.
—— fever at, *Simon*, 7127–48.

H.

Halifax, water supply of, *Dale*, 1149; *Bateman*, 6488; App. AM, BH.
—— droughts at, **60**; *Bateman*, 7408; App. BC.
Hampstead waterworks and wells, *Muir*, 3962–4, 4007.
Hampton, Thames at, **191**; App. O, AX, AY, BE, BG.
Hard and soft waters, comparison of, **174**; *Bateman*, 55–63; *Hassard*, 958–63; *Dale*, 1066–87; *Rawlinson*, 1343–6, 1364–80, 1424; *Way*, 1457–61, 1499–1528; *Clutterbuck*, 1892–3; *Duncan*, 2184–97, 2208–11, 2344–6; *Hawksley*, 2504–15, 2600–1; *Playfair*, 2646–2728; *Simon*, 2777–94; *Farr*, 2883–4; *Parkes*, 3124–42, 3200–18, 3240–5; *Beardmore*, 3344–5, 3381–7, 3429–37; *Letheby*, 3931–42; *Fulton*, 4156–71; *Simpson*, 4623–6, 4678–81; 4722–32, 4751–8; *Hawksley*, 5098–9, 5108–12, 5120; *Firth*, 5212–5319; *Jubb*, 5325–90; *Wanklyn*, 5488–97; *McClean*, 5638–42, 5672–5; *Frankland*, 6259–68, 6352–69, 6427; *Odling*, 6437–46, 6478; *Bateman*, 6680–6700; *Brodie*, 7019–27; *Miller*, 7047–58, 7087, 7093–7, 7124–6; *Smith*, 7217–22, 7259–68; *Heron*, 7343; App. D, G, AG.
Hardness of Thames water, **109**, **113**, **156**, **176**.
Harrison, John Thornhill, his evidence, 2931–3110.
—— quoted, **73**, **136**, **140**.
Hartley, his dock works, *Rawlinson*, 1351.
Hassall, his analysis of Hampshire spring waters, *Ewens*, 3753.
Hassard, R., his evidence, 546–1060, 6916–78, 7149–82.
—— quoted, **14**, **225**, **254**.
—— letter as to rainfall in Lake district, App. BM. (*See also* Hemans and Lake Project.)
Hastings sand, **90**.
Havant, springs at, *Ewens*, 3704–8.
Haweswater Lake, **43–53**; *Hemans*, 335–9, 348–62; *Hassard*, 624–55, 706–10, 768–72; *Dale*, 1169–70, 1190–1205; App. A, F.
Hawksley, Thos., his evidence, 2455–2606, 5055–5120, 7490–7537.
—— quoted, **14**, **16**, **23**, **27**, **38**, **39**, **63**, **140**, **145**, **164** **168**, **172**, **185**, **201**, **221**, **225–240**, **247**; *Duncan*, 2117–37.
Hemans, G. W., his evidence, 287–433.
Hemans and Hassard's project, **41–53**; App. F. (*See also* Lake Project.)
Hennell, Thos., his evidence, 1913–2040.
—— his plan for supplying London, **78**, **81**.
Herbert Hospital, Woolwich, water supply at, *Parkes*, 3135; *Homersham*, 6803–20.
Hertford, sewage treatment at, *Burstal*, 6853.
Heron, J., his evidence, 7269–7403.
—— quoted, **172**, **240**, **247**.
Hoddesdon, well at, *Muir*, 4050–1.
Hoffman, member of Royal Commission of 1851, **110**.
—— and Blyth, analysis of 1856, **113**, **152**, **182**; App. BG.
Holmes, S. F., his evidence, 4774–4963.
—— quoted, **240**.
Homersham, S. C., his evidence, 6762, 6837.
—— quoted, **74**, **175**.
—— works constructed by, *Bain*, 3858*a*; App. O.
Houses, number of, supplied by London companies, **124**.
Hull, water supply of, *Dale*, 1096–1119, 1302–5; *Hawksley*, 2563; *Simpson*, 4701–3.
Hungerford, River Kennett at, App. O, AX.

I.

Impure waters, *Parkes*, 3147–51.
Impurities generally of waters, **194**.
—— organic, of Thames waters, **177–218**. (*See* Quality of Waters.)
Incrustation in boilers (*see* Boilers).
Inorganic contents of water from Thames basin, **154–176**.
Interruption, possible, of flow in long conduits bringing water to London from Wales or the Lakes, **39**, **53**; *Bateman*, 240–6; *Duncan*, 2412–28; *Hawksley*, 2527, 2534–48; *Bateman*, 6643–4, 6685–6.
Iron pipes, action of soft water on, **174**; *Way*, 1490–8; *Rawlinson*, 1894–1912; *Duncan*, 2265–84; *Hawksley*, 2596–8; *Playfair*, 2675–80; *Simpson*, 4723–4, 4751–5.
Itchen River, *Parkes*, 3181, 3195–9.

J.

Jackson, John, his evidence, 4964–71.
Jamaica, water in, *Parkes*, 3240–1.
Jenyns, observations on rainfall, **62**.
Jones, Prof. Rupert, App. O.
Jubb, S., his evidence, 5320–95.
—— quoted, **172**.

K.

Kendal, water supply of, **60**; App. BC.
Kennett River, App. O, AX.
Kent Waterworks, description, statistics, &c., **23**, **122**, **124**, **145**, **208**; *Letheby*, 3863–5; *Morris*, 6094–6190; *Frankland*, 6223–40; App. P, S.
—— their future prospects, **231**.
Keswick, water supply of, *Rawlinson*, 1896–9; App. AJ.
Kimmeridge clay, **91**.
Kingston, sewage of, *Leach*, 4297–9.
Kirkstone Pass, tunnel under, *Hemans*, 399–402; *Hassard*, 717–32, 795–9.

L.

Lake Project, Hemans and Hassard's, for supplying London, **41–53**, **255**, **256**, **258** (*see* evidence of Hemans and Hassard); *Bateman*, 6703–36; App. A, D, F, AZ. (*See also* Conduit, Quality, Quantity, Rainfall, Lead Workings.)
—— Dale's, for supplying northern towns, **57**; App. Q. (*See* Dale's evidence.)
Lambeth Waterworks, general description, statistics, &c., **99**, **105**, **108**, **120**, **123**, **124**; *Simpson*, 4599; App. P.
—— future means and prospects, **231**; App. L.
Lancashire, supply of towns in, *Bateman*, 6488–6512, 6559; *Hassard*, 6919–28.
Lancaster, supply of, *Bateman*, 279; *Rawlinson*, 1896–8; *Bateman*, 6488; App, AJ.
Land, use of sewage on, **196**, **202**. (*See* Sewage.)
Langbourne, springs at, *Ewens*, 3709.
Latham, Baldwin, his sewage works at Croydon, App. O.
Leach, Stephen W., his evidence, 4240–4320.
—— quoted, **136**, **140**, **185**, **198**.
Lead, action of soft water on, **24**, **36**, **174**; *Way*, 1489–91, 1498; *Duncan*, 2299–2302; *Hawksley*, 2599; *Playfair*, 2672–4, 2697, 2725; *Simon*, 2765–6; *Parkes*, 3140–2; *Beardmore*, 3437; *Letheby*, 3870; *Simpson*, 4723–4, 4756–7; *Frankland*, 6264–5; *Homersham*, 6792; *Brodie*, 7016–8; *Miller*, 7117–21; *Smith*, 7266; App. D.
—— workings in Lake district, *Hemans*, 405–13; *Hassard*, 681–91, 758–61; *Dale*, 1170–89; *Way*, 1474–9; *Frankland*, 6212–4; App. A, D.
—— —— in Welsh district, **22**; *Hassard*, 1038–45, 1057; *Ramsay*, 1730–42; *Whalley*, 2048–65; *Bateman*, 6514–5; *Frankland*, 6212–4; App. B, D.
—— —— in Wye district, *Fulton*, 4127–41.
Leakage under constant service system, **235**.
Leamington, water supply of, *Bateman*, 273; App. AG.
Lechlade, Thames at; App. O, AX, BJ.
Lee River, generally, **72**, **127**, **164**; *Muir*, 3951–4077; *Greaves*, 5168–70. (*See also* Evidence of Mylne and Beardmore.)

Lee River, quantity of water obtained from, **142–144**; *Beardmore*, 3312–4; *Greaves*, 5177–9.
—— quality of water from, **203–7**; App. O, AX.
—— proposed reservoirs on, *Greaves*, 5132–9; *Beardmore*, 3438–9.
—— Mylne's plan for improving supply from, **72**. (*See also* Mylne's evidence.)
—— Conservancy, **129, 207**. (*See* Conservancy.)
Leeds, water supply of, *Dale*, 1147; App. AG, AM.
Leicester, water supply of, App. AM.
—— drought at, *Hawksley*, 7490–7526.
—— sewage treatment at, *Burstal*, 6853.
—— self purification of river at, *Letheby*, 3892–3; *Hawksley*, 5079–80; *Odling*, 6453–8.
Letheby, Dr., his evidence, 3859–3946.
—— quoted, **23, 164, 172, 184, 200, 201, 225, 240**; *Morris*, 6108.
—— Odling, and Abel's analyses, App. AG, AH.
—— —— quoted, **152, 159, 182**.
Levels in London to be supplied, *Hawksley*, 2582–9.
Liverpool, water supply of, general particulars, **26, 50**; *Bateman*, 277–9; *Hemans*, 310–16; *Hassard*, 901, 947–52; *Dale*, 1145–6; *Rawlinson*, 1381–1423; *Duncan*, 2101–2454; *Bateman*, 6488; *Hassard*, 6919–21; App. R, AG, AM.
—— peaty water in, *Hawksley*, 2507, 5108.
—— anxiety about interruption of conduit, **39**.
—— scarcity of supply, **58**; *Rawlinson*, 1427, 1438–40; *Duncan*, 2105, 2212–4; *Bateman*, 7416–7; App. BB, BC.
—— proposed addition to supply or supplies from new sources, **255**; *Duncan*, 2142–60, 2215–63, 2286–91, 2322–38, 2356–7, 2453–4; *Hawksley*, 2569–73.
Lime in drinking water; its effect on the animal system, **165**; *Parkes*, 3212–8; *Letheby*, 3933; *Frankland*, 6354.
Lincoln, water supply of, App. AG.
Llanwyddin Reservoir, *Bateman*, 37, 50; *Hassard*, 1046.
Locks on the Thames, *Burstal*, 3684.
Loch Katrine, *Bateman*, 42–5.
—— water of, *Wanklyn*, 5431; *Frankland*, 6273, 6313–4; *Homersham*, 6826.
—— temperature of, **39**; *Bateman*, 244.
—— aqueduct from; *Bateman*, 146–186. (*See* Glasgow, Water Supply of.)
Loch Venachar, *Bateman*, 42–44.
Loddon, River, App. O.
London Bridge Waterworks, **96**.
London clay, **87**.
—— maps of; App. AV, AW.
—— *and Westminster Water Company*, **73**.
—— (*Watford*) *Spring Water Company*, **73**.
Lords, House of, investigation in 1840, **106**.
Lowther, River, *Hemans*, 351–2; *Hassard*, 649–55, 706–10. (*See* Lake Project.)

M.

McClean, John R., his evidence, 5498–5735.
—— quoted, **140, 240**.
—— his project for the supply of London, **67, 81**; App. O, T.
McNeill, Telford, his evidence, 5815–5958.
—— his project for supplying London, **80**.
Maintenance of proposed aqueduct from Wales, *Bateman*, 231–7.
—— of aqueducts at Glasgow and Manchester, *Bateman*, 232–6.
Manchester, waterworks for, and supply of water in, **26, 50, 247**; *Bateman*, 17, 46–8, 59, 65–71, 134–6, 256–60, 277; *Hassard*, 870–3, 901, 948–51; *Hawksley*, 2509; *Simpson*, 4685; *Bateman*, 6488, 6508, 6592, 6603; *Hassard*, 6921–8; *Smith*, 7238–40, 7254, 7266–8; App. E, I, W, AG, AJ, AM. (*See also* Heron's evidence.)
—— fires in, *Bateman*, 6595–6; *Heron*, 7349–53.
—— shortness of water at, **60**; *Bateman*, 7404–8, 7427–23, 7427–30; App. BB, BC.
Manufactories in Welsh district, **21**; *Hassard*, 1026–30; App. B.
Manufacturing purposes, hard and soft water for, **170, 173**. (*See* Hard and soft water.)
Map of rivers of England and Wales and their catchment basins, **3, 252**; App. BN.
—— of Thames basin, **83**; App. Y (1, 2).
—— of districts of the several companies, **114**; App. AV.
Map of Welsh project, App. E (1, 2), BA.
—— of Lake project, App. F (1, 2), AZ.
—— of Dale's project, App. Q, 1.
—— of McClean's project, App. T (1).
—— of Bailey Denton's project, App. V.
—— of Manchester waterworks, App. W.
—— of Mylne's project, App. Z.
—— of Fulton's project, App. AA (1, 2).
—— of rainfall in Wales, App. AT.
—— of population and parishes in London, App. AW.
—— of South Staffordshire waterworks, App. BD.
—— of water supply to various provincial towns, App. BO.
Maple Durwell Spring, *Hennell*, 2014–5.
Marshall's House at Ullswater, *Hemans*, 383–4.
Martin, J., early proposal to bring water from the Colne, **73**.
Maryport, water supply at; App. AJ.
Meeson, R., his evidence, 6863–87.
—— his springs at Grays, **74–81**.
Medmenham, Thames at, App. O, AX.
—— proposed supply from, **67**; *Bateman*, 6737–8. (*See* McClean's evidence.)
Metallic veins and workings in Welsh and Lake districts. (*See* Lead workings).
Meters, water, *Simpson*, 4714–7; *Morris*, 6156–61.
Metropolis Water Act of 1852, **111, 112, 113, 127, 128, 150, 210, 238, 242**.
Metropolitan Board of Works, **128**.
Medley Lock, Thames at, App. O, AX.
Midland counties, water supply of, *Bateman*, 269–75.
Miller, Dr. W. A., his evidence, 7045–7126.
—— quoted, **23, 164–168, 172–184**.
—— member of Commission of 1851, **110**.
—— analysis of Guildford water, *Simon*, 7134.
Miller, Alexander, report on fisheries, *Bateman*, 132–3.
Mimram, River, App. O, AX.
Mineral or inorganic contents of water from Thames basin, **154–176**.
—— workings in Lake and Welsh districts. (*See* Lead workings.)
Mole River, App. O, AX.
Mont Cenis Tunnel, *Hassard*, 795–9.
Moor Park, water at, *Bain*, 3825; *Frankland*, 6338.
Morris, R., his evidence, 6094–6190.
—— quoted, **240**.
Morrys, Peter, his London Bridge waterworks, **96**.
Mortality in towns, as influenced by their water supply, *Playfair*, 2692–3, 2698, 2726–8; *Farr*, 2896; *Letheby*, 3218–26; *Bateman*, 6687–6700.
—— in Sheffield, *Holmes*, 4822–5.
Mountainous districts, supplies from, **3–64, 258**.
Muir, Jos., his evidence, 3947–4077.
—— quoted, **39, 143, 145, 175, 225, 240**.
—— letter as to future means of New River Company, App. BF.
Municipal control of water supply. (*See* Control.)
Myddelton, Sir Hugh, **97**.
Mylne, Robt. W., his evidence, 4972–5054.
—— quoted, **143**.
—— his plan for additional supply from the river Lee, **72, 81**; App. Z.

N.

Navigation of the Severn, *Bateman*, 282–5, 6662; *Hawksley*, 2464.
—— of the Thames, *Harrison*, 3091; *Burstal*, 3611, 3614–3627; *Hawksley*, 5113–5.
Newcastle-on-Tyne, water supply of, and effects of drought in 1868, **58, 60**; App. I, AG, AM, BB, BC.
Newram, spring at, *Hennell*, 2014–5.
New River Company, history, description, statistics, &c., **97, 105, 115, 123, 124, 142**; *Muir*, 3950–4077; *Mylne*, 4976–82; App. P.
—— future means and prospects, **231**; App. BF.
—— interruption by frost, **39**; *Simpson*, 4617.
New York, water supply of, *Simpson*, 4699.
Nile, water of, producing dysentery, *Parkes*, 3190–2.
Nitrogen, nitrates, and nitrites in water, **194**; *Parkes*, 3152–61; *Miller*, 7072–7. (*See also* Evidence of Frankland, Odling, Wanklyn, Brodie, Angus Smith, and Quality of Waters.)

Nomenclature, hydraulic, *Rawlinson*, 1426.
Norwich, water supply of, *Hawksley*, 2561; App. AG, AJ, AM.
Nottingham, water supply of, App. AM.

O.

Odling, Dr., his analysis of various waters, **17, 153**; App. D, AG, AH, AX, BE.
(*See* Frankland and Odling.)
—— his evidence, 6433–6484.
—— opinions on sewage irrigation, *Burstal*, 6851–62.
—— quoted, **24, 164, 172, 184, 186, 200, 201, 202**; *Frankland*, 6386.
Oldham, water supply of, *Bateman*, 277, 6488.
Oolites, springs in, **70, 92**; App. O. (*See* Evidence of Brown and Bravender.)
Organic matters in water, **113, 177–218**; *Bateman*, 136–7, *Hassard*, 983–1025; *Playfair*, 2681–2; *Simon*, 2763–4, 2807–12; *Letheby*, 3880–8; *Wanklyn*, 5401–97; App. BG.
(*See also* Evidence of Frankland, Miller, Angus Smith, Brodie, Odling; also Quality of Water.)
Ormsby, A. S., his evidence, 4443–4560.
Orton, Thos., his evidence, 4172–4239.
Otter's Pool spring, near Watford, *Clutterbuck*, 1833; App. O, AX.
Oxford, Thames at, App. O, AX.
—— drainage of, *Brodie*, 6980–5; App. O.
—— water supply of, *Bateman*, 275.
—— clay, **91**.

P.

Pant Mawr lead mines, *Whalley*, 2053; App. B.
Paper mills on the Thames, *Thorpe*, 5774–93.
Paris, supply of, *Hassard*, 959–62; *Hawksley*, 2544–51, 2602; *Playfair*, 2696–7; *Farr*, 2894–5; *Letheby*, 3932; *Simpson*, 4729*a*–32; *Hawksley*, 5098.
Parkes, Dr. E. A., his evidence, 3111–3255.
—— quoted, **164, 172, 184, 201**.
Peat, effect of, in water generally, *Hassard*, 992–1000; *Hawksley*, 2504–12; *Playfair*, 2685; *Beardmore*, 3431–6; *Letheby*, 3870–2; *Hawksley*, 5108; *Miller*, 7059–61, 7091; *Smith*, 7212–4, 7255–8, 7264–5.
—— in Lake district, *Hemans*, 308, 341–7; *Hassard*, 624–9; *Dale*, 1127–41; *Frankland*, 6203–10, 6313–4; App. A, D.
—— in Welsh district, **23, 36**; *Bateman*, 134; *Ramsay*, 1713–20; *Frankland*, 6203–10, 6313–4; *Bateman*, 6657–62; App. B, D.
—— in water at Manchester, Liverpool, Glasgow, and Sheffield, *Bateman*, 134–6; *Simpson*, 4685; *Holmes*, 4814–9; *Bateman*, 6657–62.
Penrith, water supply of, *Hassard*, 761–2; App. BB.
Percolation in Thames basin, *Harrison*, 2958–66.
Permeable and impermeable strata in Thames basin, **82–94**; *Harrison*, 3041–67.
Pipes in lake conduit, *Hemans*, 428–9; *Hassard*, 742–3, 778–95, 825–30.
—— wooden, in London streets, replaced by iron, **100**.
Playfair, Dr. Lyon, his evidence, 2634–2728.
—— quoted, **24, 164, 172, 184, 240**.
Plumstead waterworks, *Homersham*, 6767–6837.
Plymouth, water supply of, App. AG.
Pole, William, report on Lake district, App. A.
—— quoted, **52**.
—— report on Welsh district, App. B.
—— quoted, **17, 21, 22, 23**.
—— report on Bala Lake, App. C.
—— report on Thames basin, App. O, AY.
—— quoted, **153, 185**.
Pollution of Rivers, Way, 1519–28; *Hawksley*, 2553.
—— —— Commission on. (*See* Commission.)
Poor, water supply to the, **244, 248**; *Simon*, 2743–4, 2830–3; *Beardmore*, 3366–80; *Simpson*, 4621, 4707–17, 4744–50; *Hawksley*, 5100–5, 5116–9; *Greaves*, 5162–7, 5202–10; *Rendle*, 6750–61.
Population of London, **219–223**; *Bateman*, 3–15; *Hassard*, 865; *Hawksley*, 2502; App. E, AH, AW.
—— of Thames basin, **179**; *Hawksley*, 2591–5.
—— on the Severn, *Hawksley*, 2591–5.
Portland stone and sands, **91**.
Potteries, Staffordshire, water supply of, *Hassard*, 593–604.
Pressure in mains, reduced by constant service system, **235**.
Preston, water supply of, *Bateman*, 277, 6488; App. AG, AJ, AM.
—— drought at, **60**; App. BC.
Present water supply of London, **95–129**.
Previous sewage contamination of water, **194**; *Morris*, 6107–13; *Brodie*, 7006–7; *Miller*, 7072–7123; App. D, AJ.
(*See* Evidence of Frankland, Odling, Brodie, and Quality of Water.)
Provincial towns, water supply of, **10, 48, 53, 57, 251–6, 264**; *McClean*, 5587–95, 5653–71, 5683–5725; *Bateman*, 6488–6512; *Hassard*, 6919–28; App. BO.
—— proposed to be supplied by Lake project, *Hemans*, 310–16; *Hassard*, 590–604, 772–7, 852–9, 883–901, 947–57.
—— —— by Welsh project, *Bateman*, 269–275.
—— —— by Dale's project, *Dale*, 1145.
Public supplies of water, **248**.
Pump waters in London, *Letheby*, 3873–9.
Pumping, cost of, *Hawksley*, 2573–8; *Quick*, 6057–8; *Bateman*, 6604–6, 6656–7; App. K.
—— necessary under Welsh and Lake projects, **35, 53**.
—— power of London water companies, **124**.
Putrefaction in water, **174**.
Purification and conservancy of the Thames and Lee, *Simon*, 2815–21, 2837–42; *Burstal*, 3581–95, 3632–68; *Letheby*, 3882–91. (*See* Conservancy.)
Purchase of water companies' interests, *Hawksley*, 2529–33.
(*See also* Welsh project, Financial details, and Control of water supply.)

Q.

Quality of waters supplied to London, and of the water generally from the Thames basin, **104, 128, 149–218, 248, 260**; *Rawlinson*, 1359–60; *Clutterbuck*, 1805–10; *Simon*, 2751–71, 2804–42; *Beardmore*, 3329–30; *Leach*, 4289–96; *Simpson*, 4581–5, 4600, 4623–37, 4656–62, 4678–97; *Wanklyn*, 5398–5497; *McClean*, 5555–8; *Quick*, 5996–6010, 6064–9; *Hawksley*, 2504–12, 2553–6, 5074–83, 5098, 5106–12, 5120; App. D, O, AF, AG, AH, AK, AJ, AX, AY, BE, BG.
(*See also* Evidence of Frankland, Odling, Farr, Miller, Brodie, Angus Smith, Playfair, Letheby, Parkes.)
—— of water from Lake district, **52**; *Hemans*, 300, 306–8; *Way*, 1454–83; *Frankland*, 6200–20; App. A, D, F.
—— of water from Welsh district, **17, 24, 36**; *Bateman*, 57–8, 134–45; *Hemans*, 300; *Hassard*, 979–1045; *Simpson*, 4685; *Frankland*, 6200–20; App. B, D, E.
Quantity of water at present supplied to London, **124**; *Bateman*, 6–10; *Hemans*, 293–4; *Hawksley*, 2467–8, 2516–23; App. N.
—— which will probably be hereafter required for London supply, **219–229, 261**; *Hemans*, 295–9, 317; *Hassard*, 561–2, 859–82, 899–901; *Rawlinson*, 1408–14; *Hawksley*, 2491–2503; *Simon*, 2798–2803; *Harrison*, 3072–85; *Beardmore*, 3326–8; *Fulton*, 3510–2; *Simpson*, 4647–51, 4718–22, 4759–64; *Hawksley*, 5088–92; *Greaves*, 5142–54, 5205–9; *McClean*, 5597; *Quick*, 6059–63, 6082–93; App. E.
—— allowed generally per individual, **224–228**; *Bateman*, 5–20; *Parkes*, 3221–6; *Letheby*, 3927–30, 3943–6; *Muir*, 4058–63; App. I.
—— consumed in various provincial towns, **226**; *Bateman*, 140–2; *Duncan*, 2221–6, 2251–3, 2360–77; *Holmes*, 4802–11; App. AM.
—— which the London companies are empowered to take from the Thames, and which they can hereafter supply, **138, 232**.
—— flowing in the Thames and the Lee, **134**. (*See* Volume.)
—— available from the Thames and the Thames basin, **131–148, 259**; *Denton*, 1532, 1546–7, 1683, 1691; *Beardmore*, 3321–2; *Leach*, 4300–20; *Simpson*, 4572, 4611, 4640–51, 4684; *Hawksley*, 5055–73, 5083–96, 5106–7; *Greaves*, 5180–7; *McClean*, 5637–8; *Thorpe*, 5747–8; *Quick*, 6005–9.
—— available from the River Lee, **142–4**.
—— available from the chalk, **145–7**.
—— available from Lake district, **45**. (*See* Evidence of Hemans and Hassard.
—— available from Welsh district, **11–16**; *Bateman*, 108–110, 122, 7423–6.
Quick, J., his evidence, 5982–6093.
—— quoted, **136, 140, 185, 240**.
—— on the cost of pumping and filtration, App. K.
—— on the future means of certain water companies, App. L.

R.

Rainfall, generally, **61, 62**; *Symons*, 441; *Rawlinson*, 1425–40, 1448–52; App. BB, BC.
—— at Greenwich, **62**; *Hawksley*, 7526.
—— in Thames basin, **84, 133**; *Harrison*, 2943–3040, 3110; *Beardmore*, 3267–89; *Simpson*, 4671–7; *McClean*, 5509–23, 5643–5; App. AC, AD, AE.
—— in Upper Thames basin, **69**; *Brown*, 6838–42; *Bravender*, 6895–9, 6902–3; *Beardmore*, 7444; App. BJ.
—— on the Lee, *Muir*, 4032–9; *Beardmore*, 7444–57.
—— in the Welsh district, **13, 14, 37**; *Bateman*, 23–36, 103–122; *Hemans*, 421–8; *Hassard*, 467–545, 964–78; *Rawlinson*, 1337–41; *Clutterbuck*, 1849–64; *Duncan*, 2407–10; *Hawksley*, 2487; *Symons*, 2729, 2735–6; *Beardmore*, 3290–5; *Bateman*, 6524–39, 7424; App. E., AT.
—— at Bala, *Duncan*, 2287–90, 2332.
—— in the Wye district, *Fulton*, 3454–3507, 4078–92.
—— in the Lake district, **45**; *Bateman*, 23–6, 103–4; *Hemans*, 309–33; *Symons*, 435–545; *Hassard*, 607–23; *Hawksley*, 2470; *Symons*, 2730–5; *Beardmore*, 3300–3; App. B.M.
—— in Lancashire and Yorkshire, *Bateman*, 104; *Duncan*, 2107–37; *Holmes*, 4790–4801; *Bateman*, 6485, 6490–6; *Hawksley*, 7537.
—— in Scotland, *Bateman*, 26–36, 108, 6485.
Ramsay, Professor, his evidence, 1707–81.
Rateable property in London, **26**; *Bateman*, 262–8; App. E.
Rates for water, **103, 250, 263**; *Bateman*, 65–71; *Hemans*, 414–20; *Simpson*, 4771–3.
—— in Manchester, Glasgow, Liverpool, and other provincial towns, **28**; *Bateman*, 189–206; *Hassard*, 873; *Duncan*, 2434–52; *Holmes*, 4907–15, 4937–8; *Bateman*, 6744.
(*See also* Heron's evidence.)
—— proposed for London, **28, 250, 263**; *Bateman*, 247–68; *Hassard*, 910–44; *Bateman*, 6739–46.
Ravensbourne River, **122**; *Morris*, 6100–3, 6138–9, 6189.
Rawlinson, Robert, his evidence, 1306–1425, 1426–1452, 1894–1912.
—— quoted, **14, 140, 164, 168, 172, 225.**
Reading, Thames at, App. O, AX.
—— drainage of, App. O.
Registrar General's Reports, examples of, App. AJ.
—— referred to, **127, 152, 159, 182, 194, 211**; *Simpson*, 4739–40; *Greaves*, 5171–6.
(*See* Quality of Water.)
Remington, S., his evidence, 4321–4442.
—— his project for the supply of London, **56.**
Rendle, W., his evidence, 6749–61.
—— quoted, **240.**
Repairs of mains, **235.**
Reservoirs, on, generally, **63**; *Rawlinson*, 1320–5, 1348–58, 1441–7; *Hawksley*, 7498–7529.
—— of present London water companies, **124.**
—— proposed on the Thames, **139–141**; *Denton*, 1594–5, 1635–40; *Harrison*, 3092–3109; *Beardmore*, 3322, 3399–421; *Burstal*, 3612–3, 3638–9, 3664, 3680; *Leach*, 4248, 4271–86, 4300–18; *Simpson*, 4572–611, 4646; *Hawksley*, 5071–3, 5093–6; *McClean*, 5524–8; *Thorpe*, 5748–59, 5812–4; *Quick*, 6008.
—— proposed on the Lee, **143**; *Beardmore*, 3313–4; 3438–9; *Muir*, 3972–8, 4019–21, 4029; *Mylne*, 4983–5054; *Greaves*, 5178–9.
—— belonging to Welsh project, **6, 8, 15, 16, 40**; *Bateman*, 36–52, 100–102, 115–6; *Hassard*, 1033–7, 1046–55; *Ramsay*, 1724–9, 1749–50, 1777–80; *Hawksley*, 2463, 2469–89; *Bateman*, 6513–4, 6560–3, 6667–8; *Hassard*, 6929–33, 7150–67, 7529; App. AP.
—— belonging to Lake project, **47**; *Hassard*, 818–24, 839–45, 6964–74.
—— belonging to Wye project, *Fulton*, 3475–83, 3508–9, 3519–20, 3557–9.
Reservoir, bursting of, at Sheffield, *Holmes*, 4782–5.
Rivers of England and Wales, and their catchment basins, **3, 252**; App. BN.
Rivers Pollution Commission. (*See* Commission.)
Rivington Pike Works, *Bateman*, 278–9; *Duncan*, 2101–2454. (*See* Liverpool, water supply of.)
Rochdale, water supply of, *Bateman*, 277.
—— drought at, **60**; App. BC.
Roget, Dr., **104.**
Royalty for water, *Whalley*, 2078.
Rugby, sewage treatment at, *Burstal*, 6853.

S.

Salford, see Manchester.
Sands, Bagshot. (*See* Bagshot Sands.)
—— Hastings, **90.**
—— Tertiary, **87.**
Scour of Thames, *Leach*, 4271–7, 4302–3.
Sections, geological, **85**; App. Y 3.
—— of Thames, *Harrison*, 2968; App. AB.
Self-purification of rivers and streams, **180**; *Farr*, 2852–64; *Parkes*, 3180–8, 3195–9, 3250–5; *Letheby*, 3891–7; *Leach*, 4291–6; *Hawksley*, 5075–82; *Wanklyn*, 5482–5; *Frankland*, 6372–4; *Odling*, 6447–58; *Brodie*, 6982–91, 7010–14; *Miller*, 7062–71, 7088–90; *Simon*, 7135–41; *Smith*, 7188–200, 7241–4; App. O. AX.
Separation of water supplies for different purposes, *Simpson*, 4735–8, 4761–4; *Greaves*, 5210–1; *McClean*, 5579–82; *Quick*, 6024–5; *Brown*, 6841.
Separating weirs in Manchester Waterworks, *Bateman* 134–6.
Seven Springs, *Bravender*, 6901; App. O.
Severn, River, area of basin, *Bateman*, 6515*a*.
—— towns and population on, *Hawksley*, 2591–5.
—— head streams of, **6**; *Bateman*, 22; App. B, E. (*See* Welsh Project.)
—— interests upon, **38**; *Whalley*, 2042–96; *Hawksley*, 2460–4, 2580–1; *Simpson*, 4613–6; *Bateman*, 6662–6.
—— navigation of, *Bateman*, 282–5; *Hawksley*, 2464.
—— volume of, *Hawksley*, 2603–6; *Simpson*, 4765–9. (*See* Welsh Project.)
Severn Valley, danger of reservoirs in, **40.**
Sewage, utilization and treatment of, **196, 202**; *Denton*, 1606–22, 1675–81; *Farr*, 2886–93; *Parkes*, 3230–6; *Simpson*, 4638–9, 4663–70; *Frankland*, 6376–9; *Brodie*, 6992–4, 7036–40; *Burstal*, 6851–62; *Miller*, 7078–80; *Smith*, 7204–7; App. O, AX.
—— in drinking water, effects of, *Parkes*, 3114–23. (*See* Quality of Water.)
—— exclusion of, from the Thames, **68, 195–202**; *Hawksley*, 2553–4; *Beardmore*, 3331–43. (*See* Conservancy.)
—— Act, 1867, **126.**
Sheffield, water supply of, *Holmes*, 4774–4971; *Bateman*, 6555–8; App. I, AG, AM.
—— shortness of water at, **60**; App. BC.
Shiplake Mill, App. O.
Shortlands, well at, *Morris*, 6108.
Simon, J., his evidence, 2737–2843, 7127–48.
—— quoted, **164, 172, 184, 201, 240, 247.**
Simpson, James, his evidence, 4561–4773.
—— quoted, **23, 38, 136, 140, 185, 225, 240.**
—— gaugings of the Thames, *Harrison*, 2967–9.
—— letter on the cost of pumping and filtration, App. K.
—— letter as to future means of water companies, App. **L.**
Smith, Dr. Angus, his evidence, 7183–7268.
—— quoted, **23, 164, 172, 184, 201**; *McNeill*, 5888.
Smith, Miles H., mode of analysis. *See* Wanklyn's evidence.
Snow, Dr., quoted, *Farr*, 2881; *Letheby*, 3910.
Soap, waste of by hard water, **157, 170–3**; *Bateman*, 59–63; *Dale*, 1069–74; *Way*, 1516–9; *Hawksley*, 2567–8; *Playfair*, 2646–7; *Simon*, 2782–4; *Hawksley*, 5098; *Firth*, 5217–319; *Bateman*, 6680, 6690–2.
Soap test, Clark's, **158**; App. G.
Soft and hard water, comparison of. (*See* Hard and soft water.)
Softening process, Clark's, **175–6, 178**; *Parkes*, 3207; *Bain*, 3812–58; *Letheby*, 3937; *Muir*, 4026–8; *Morris*, 6126; *Frankland*, 6262–4; *Homersham*, 6762–6837; App. G, O.
Sources of water supply other than mountainous districts, **65–94.**
South Cerney Spring; App. O.
(*See* Evidence of Brown and Bravender.)
South Essex Waterworks, **123**; *Meeson*, 6863–87.
Southampton, cholera and fever at, *Parkes*, 3120, 3162 *Letheby*, 3900.
—— river at, *Parkes*, 3195–9.
Southport, water supply of, App. AG.
Southwark, deficient supply of water in, *Rendle*, 6750–61; App. BL.
Southwark and Vauxhall Water Company, general description and statistics, **102, 105, 121, 123, 124**; App. P.
—— future means and prospects, **231**; App. L.
Springs in Thames basin generally, **85–94.**
—— in oolites and Upper Thames, **70.**
(*See* Brown's and Bravender's evidence.)

Springs at Chadwell and Amwell, **97**; *Muir*, 3951–67.
—— at Gravesend, *Barlow*, 5961–81.
—— at Grays, **78**; *Greaves*, 5194–5201; *Meeson*, 6863–87.
—— on and near the Basingstoke Canal, *Hennell*, 1947, 2012–5.
—— in Hampshire, **78**; *Ewens*, 3687–3796.
—— in the Severn, *Hawksley*, 2606.
—— at Bradford, *Harrison*, 3024.
Staffordshire towns, supply of, *Bateman*, 269; *McClean*, 5587–95, 5653–71, 5683–5735.
—— *South*, waterworks, App. BD. (*See* McClean's evidence.)
Staines, Thames at, App. O, AX, AY, BE.
Stalybridge, water supply of, *Bateman*, 277, 6488.
Stanmore, proposed reservoir at, **7, 8**. (*See* Bateman's evidence.)
Statistics of present water supply, **124**.
Stephenson, Robert, his report on supplies from the chalk at Watford, **73**; *Homersham*, 6822.
St. Helen's, water supply of, *Bateman*, 277.
St. John's Bridge, Lechlade, Thames at, App. O.
Stockport, water supply of, *Bateman*, 277; App. BC.
Storage reservoirs, on, generally, **63**; App. BB.
Storage, in Welsh district, **15**.
—— in Lake district, **46**.
Stourbridge, water supply of, *Bateman*, 272.
Strata, permeable, **85–94**.
Stye, rainfall at the, *Symons*, 441–458.
Subterranean stores of water in Thames basin, **85–94**; *McClean*, 5520; *Brown*, 6840–50.
Summary of conclusions and recommendations by the Commission, **257–264**.
Sunderland, water supply of, App. AG, AM.
Suspicious waters, class of, *Parkes*, 3147–61.
Symons, G. T., his evidence, 434–545, 2729–36; App. AT.
—— quoted, **14, 45, 62**; *Bateman*, 6524.
—— letter on rainfall in lakes, App. BM.
Syreford Spring, *Bravender*, 6901; App. O, AX.

T.

Taunton, his gaugings of Thames, &c.; App. BJ.
Taylor, John, his evidence, 7458–89.
—— reports on gravitation supplies, and drought in 1868, **59–60**; App. BB, BC.
Tea, soft and hard water in making, **167–8**; *Way*, 1505–16; *Frankland*, 6361.
Teddington lock and weir, *Burstal*, 3607–9; *Leach*, 4259–68, 4306–10.
Telford, Thomas, member of Royal Commission of 1828, **104**.
—— his proposed new sources of supply, **73–106**.
Temperature of Glasgow conduit, **39**; *Bateman*, 244.
Tertiary sands, **87**.
Thame, River; App. O, AX.
Thames, towns and population on the, *Hawksley*, 2591–5.
—— volume of. (*See* Volume. Quantity.)
—— not affected by drought of 1868, **64**.
—— Conservancy Act, **126, 150, 196–202**.
—— and Severn Canal; App. BJ, BK.
Thames-head spring, *Bravender*, 6899; App. O, AX.
Thames basin, on the supply of water from the, present and future, and on its geological and hydrological character, **66–70, 82–94, 130–218**; App. H, O. (*See* Evidence of *Denton, Clutterbuck, Brown, Brown. Bravender, Harrison, Beardmore, Burstall, Thorpe, Leach; also* Quantity and Quality of Water.
—— maps of the, **83**; App. Y (1, 2).
Thirlmere Lake, **43–53**; *Hemans*, 362–78; *Hassard*, 656–72, 741, 768–771; App. A. (*See* Lake Project.)
Thorpe, J. H., his evidence, 5736–5816.
—— quoted, **140–198**.
Tide at Richmond, *Burstal*, 3672–4.
Tidal action in the Thames, *Hawksley*, 5059–69.
Trefeglwys reservoir, *Bateman*, 41–46, 50; *Hassard*, 1048–9.
Trench, Dr., report on Liverpool waters, *Duncan*, 2187.
Tributaries to the Thames, *Harrison*, 3020–4; App. O, AX.
Trinidad, water in, *Parkes*, 3241.
Tunnel under Kirkstone Pass, *Hemans*, 399–402; *Hassard*, 717–32, 795–9.
—— under Matterdale Common, *Hassard*, 712–7, 729.
Tyler, Captain, investigation as to water supply in East London, **205**; *Beardmore*, 3393–4.
Typhoid fevers communicable by drinking water, *Parkes*, 3114–3123, 3169–76.

U.

Ullswater Lake, **43–53**; *Hemans*, 373–99; *Hassard*, 673–704; *Dale*, 1151–89; App. A, D, F.
Useable waters, *Parkes*, 3147–51.

V.

Van mine, *Hassard*, 1039; App.B.
Varnish for iron pipes, *Rawlinson*, 1906–11; *Duncan*, 2278–82; *Hawksley*, 2596; *Bateman*, 6586–7.
Vauxhall Water Works Company, **102**.
Verulam, River, proposed supply from, **73**.
Vienna, water supply of, *Letheby*, 3932.
Voelcker, his analysis of springs at Grays, *Meeson*, 6879.
Volga, River, 3190.
Volume of water in the Thames, **131–141**; *Harrison*, 2966–3040, 3086–3110; *Beardmore*, 3260–80, 3315–22, 3424–8; *Burstal*, 3628–31; *Leach*, 4243–70; *Simpson*, 4569–71, 4601–11; *Hawksley*, 5067–8; *McClean*, 5517–20, 5715–8; *Bateman*, 6515*a*–22, 6540–54, 7442–4; *Taylor*, 7472–89.
—— in the Upper Thames, *Brown*, 6840; *Bravender*, 6901; App. BJ.
—— in the River Lee, **142–144**. (*See* Lee, River.)
Vyrnwy, River, App. B, D, E. (*See* Welsh project and Bateman's Evidence.)

W.

Wakefield, water supply of, *Miller*, 7089; App. AG.
Wallingford, sewage of, *Leach*. 4290.
Walsall, water supply of, *Bateman*, 269.
Wandle, River, **202**; *Burstal*, 3656–7; App. O, AX.
—— proposed supply from, **73**.
Wanklyn, Professor, his evidence, 5396–5497.
—— quoted, **184, 209**.
—— remarks on the London waters, App. AK.
—— his modes of analysis, *Frankland*, 6196–9. (*See also* Brodie's evidence.)
Warehouses in Southwark, App. BL.
Warrington, water supply of, *Bateman*, 277; *Duncan*, 2331.
Warwick, water supply of, *Bateman*, 272.
Washing, use of hard water for, **170, 173**. (*See* Hard and soft water.)
Waste of water, **235**; *Hawksley*, 2490; *Greaves*, 5204–9; App. I. (*See also* Constant service.)
Waterworks Clauses Act, 1847, **236**.
Watford, proposed supply from, **73, 110**; *Clutterbuck*, 1834–5; *Bain*, 3799, 3858; *Homersham*, 6822–3.
—— springs at, App. O, AX.
Way, J. T., his evidence, 1453–1528.
—— quoted, **24, 164, 168, 172**.
—— analysis of Lake waters, App. F.
Weald clay, **90**.
Wednesbury, water supply of, *Bateman*, 272.
Weirs, effect of, on the Thames, App. O.
Wells in London, *Letheby*, 3873–9; *Wanklyn*, 5431, 5473–5; *Frankland*, 6339–41; App. AG.
—— of New River Company, *Muir*, 3968–4077.
—— of Kent Water Company, **122**. (*See* Morris's evidence.)
—— in Thames basin, *Clutterbuck*, 1790–3, 1801–3, 1812–26, 1872; *Harrison*, 3048.
—— at Charing Cross, **123**.
—— in New Red Sandstone, *Duncan*, 2101, 2175–2211, 2347–59.
—— at Cirencester, *Bravender*, 6901.
—— at Crossness, *Barlow*, 5968.
—— at Croydon. (*See* Croydon.)
—— at Grenelle, *Odling*, 6574.
Welsh project, Bateman's, for supplying London, **4–10**; App. E. (*See* Bateman's Evidence.)
—— summary of evidence as to, **11–29**.
—— remarks by the Commission on, **30–40, 258**.
—— gathering ground and district generally, App. B, E, BA.; *Bateman*, 22.
—— conduit. (*See* Conduit.)
—— reservoirs. (*See* Reservoirs.)

Welsh project, quality of water. (*See* Quality of Water.)
—— Duncan's remarks on, *Duncan*, 2404–28.
—— Simpson's remarks on, *Simpson*, 4613–19.
West Indies, water in, *Parkes*, 3240–2.
West Middlesex Water Company, general description and statistics, **101**, **105**, **118**, **123**, **124**; App. P.
—— future means and prospects, **231**; App. L.
Wey, River, App. O, AX, AY, BE.
Whalley, G. H., his evidence, 2041–2096.
Whitehaven, water supply of, App. AJ.
—— iron pipes at, *Rawlinson*, 1906.
Whitewater, spring at, *Hennell*, 2013.
Wholesome waters, class of, *Parkes*, 3147–51.
Wigan, water supply of, *Bateman*, 277–9, 6488.
Williamson, Professor, analysis of Kent Company's water, *Morris*, 6190.
Windermere, rainfall at, **62**.
—— supply to Liverpool from, *Hawksley*, 2572–3.
Windsor, drainage of, *Leach*, 4289–96; App. O.
—— lead in water at, *Simpson*, 4757.
—— Thames at, App. O, AX.
Winterwell Spring, Bravender, 6901.
Wolverhampton, water supply of, *Bateman*, 269–72; App. AM.
Woolwich, wells at, *Morris*, 6120–1.
Worcester, water supply of, App. AG.
Works of the various London companies, **124**.
Wormley, well at, *Muir*, 4000.
Worthing, water supply of, App. AJ.
—— sewage treatment at, *Burstal*, 6853.
Wye project, Mr. Fulton's, **54**; *Fulton*, 3446–3571.
—— River, head waters of the, *Bateman*, 22.

Y.

York, water supply of, App. AG.
—— Buildings Waterworks, **98**.
Yorkshire waters, quality of, *Way*, 1487–8.

ALPHABETICAL LIST OF WITNESSES,

With references to the principal Subjects of their Evidence, and the Numbers of the Questions corresponding thereto.

BAIN, ALEXANDER (29th May 1867) - - *Page* 228
References to Reports of the Board of Health, and of the Chemical Commission of 1851, on the metropolis water supply; and recommendation of the water from the chalk - - *Question* 3797–3858
List of waterworks constructed by Mr. S. C. Homersham to supply spring water softened by Dr. Clark's process (at end of evidence).

BARLOW, P. W. (27th June 1867) - - - *Page* 327
Information as to water procurable from chalk springs in North Kent - - - *Question* 5959–81

BATEMAN, JOHN FREDERIC (6th February 1867) - *Page* 1
Population of the metropolis, present and prospective - - - - - *Question* 3–4
Quantity of water supplied in London - - 5–15
Quantity supplied in Glasgow, Manchester, and other towns - - - - - 16–20
Sources most eligible for the water supply of London - - - - - 21
Rainfall of Welsh district - - - 23–24
Area of ditto - - - - - 25–26
Rainfall, and proportion available - - 26–36
Reservoirs for storage - - - - 36–52
Additional districts available - - - 45
Gauging of the streams - - - 53–54
Advantage of soft water - - - 55–63
Quality of water from Wales - - - 57
Supply of Glasgow from Loch Katrine - 64–71
Compensation to mills - - - - 73
Fisheries - - - - - 74–98
Levels of various parts of the work 100–102
Second Examination (7th February 1867) - *Page* 10
Rainfall in various parts of England - *Question* 103–8
Reservoirs and storage of water - - 109–115
Levels of various parts of the work - - 116–118
Rainfall - - - - - 119–122
Fisheries - - - - - 123–133
Peat in Welsh district, and its effect on the water - - - - - 134–136
Organic impurity in Welsh waters - - 137–139
Quantity of water consumed in Glasgow and Manchester - - - - - 140–142
Analyses of Welsh waters - - - 143–145
Description of conduit conveying Loch Katrine water to Glasgow - - - - - 146–158
Conduit proposed to bring water from Wales to London - - - - - 158
General reasons for his preference of the Welsh district for the supply of London - - - 158–167
Further evidence as to the Welsh conduit - 168–175
Ditto as to the Glasgow conduit - - 176–186
Financial arrangements in Glasgow consequent on the introduction of the new waterworks - 187–201
Ditto in Manchester - - - - 202–206
Estimate for Welsh conduit - - 207–216
Reservoirs - - - - - 217–218
Further evidence as to Welsh conduit - 219–230
Maintenance of conduit - - - 231–237
Financial arrangements for Welsh project - 238–239
As to the danger of having the population of London dependent on one supply of water; of interruptions to the flow in the conduit by frost, &c. - 240–246
Financial arrangements proposed; rates for water, &c. - - - - - 267–268
Provincial towns on the line of conduit proposed to be supplied - - - - 269–275
Other projects for supplying London - - 276
Remarks on the water supply of several towns in the manufacturing districts - - - 277–279
Maps promised - - - - 280–281
Interference with the navigation of the Severn 282–285
Length of time necessary to complete Welsh works - - - - - 286
Third Examination (4th March 1868) - - *Page* 356
Particulars of rainfall in different localities, indicating the effect of mountain ranges - *Question* 6485
Particulars as to the Loch Katrine aqueduct *Qu.* 6485–7
Particulars as to the supply of water to manufacturing towns in the North of England - 6488–6512
Further explanations as to various points in regard to the Welsh project - - - 6513–5a
Volume of the Thames in drought - 6515a–22
As to the rainfall in the Welsh district - 6523–39
Fourth Examination (5th March 1868) - - *Page* 367
Gaugings of the volume of the Thames in dry seasons - - - *Question* 6540–54
On the water supply of Lancashire manufacturing towns - - - - 6555–9
Explanations as to the reservoirs proposed in the Welsh project - - - - 6560–63
Explanations as to the estimates for the Welsh project, and as to the proposed arrangements for the delivery of water in London - - - 6564–74
Explanations as to the financial and administrative details for the Welsh project, and further particulars as to the distribution - - - 6575–88
As to the constant service system; with particulars as to the advantages of its application in Manchester - - - - 6589–6604
Further financial details; and comparison of cost of getting certain quantities of water from the Thames and from Wales respectively - - 6604–15
Table of minimum and average rainfall - - 6615
Fifth Examination (11th March 1868) - - *Page* 386
Further explanations as to the comparative estimates for the Welsh project - - *Question* 6616–56
As to peat in the water - - - 6657–62
Effect of the Welsh project on the navigation of the Severn - - - - - 6662–6
As to the danger of large reservoirs - - 6667–8
As to the danger of freezing in the aqueduct 6669–79
Hard and soft water - - - 6680–4
Danger of interruption to the flow in the conduit - - - - - 6685–6
Influence of the quality of water supply on the mortality of towns - - - 6687–6700
Area of catchment ground available for Welsh scheme - - - - - 6701–2
Objections to Messrs. Hemans and Hassard's project for supplying London from the Lakes - 6703–36
Objections to Mr. McClean's project - 6737–8
Financial result of the Welsh scheme - 6738–47
Sixth Examination (9th December 1868) - *Page* 464
Information as to the effects of the drought of 1868 on the water supply of Manchester - *Question* 740–8
Ditto as regards Halifax and Dublin - - 7408
Ditto as regards Glasgow - - - 7409–12
Ditto as regards Blackburn - - 7412–15
Ditto as regards Liverpool - - - 7416–7
Further observations on drought at Manchester, 7417–7423
Calculations as to the rainfall in and supply from the Welsh district - - - - 7423–4
Quantity supplied to London in 1866–7–8 - 7424–6
Further general remarks on the drought - 7427–41
Volume of the Thames in 1868 - - 7442–3

BEARDMORE, NATHANIEL (16th May 1867) - *Page* 202
On the rainfall and quantity of water flowing in the Thames and the Lea - - *Question* 3255–89
Rainfall in the Welsh district - - 3290–5
Flow of the Thames - - - - 3296–8
On the Welsh and Lake projects for supplying London - - - - - 3299–3311
Capabilities of the river Lea - - - 3312–4
Ditto of the Thames - - - 3315–22
Analysis of Thames water at Oxford - 3323–5
Quantity of water necessary per head per diem 3326–7
Capacity of the Thames as a source of supply - 3328
Quality of water from Thames and Lea - 3329–30
Drainage of towns on the river - - 3331–5
Further remarks on additional supplies from the Thames and Lea - - - - 3336–43

Hard and soft water - - *Question* 3344–5
Constant service system - - - 3346–80
Hard and soft water - - - - 3381–7
As to the connexion of the water supply with the cholera in the east of London - - 3388–96
Flow of the Severn - - - - 3397–8
Capability of the Thames basin for increased supplies. Adaptation of large reservoirs - - 3399–3421
Flow of the Severn - - - - 3422–3
Flow of the Lea - - - - 3424–8
Hard and soft water - - - 3429–36
Action of soft water on iron pipes - - 3437
Capability of the Lea for increased supply - 3438–9
Difficulty of introducing into London a delivery of water by gravitation - - - 3440–5
Second Examination (9th December 1868) - *Page* 477
Information as to the effects of the drought of 1868 on the Lea and the Thames - *Question* 7444–57

Bravender, John (18th March 1868) - - *Page* 421
Information as to the geology of the upper basin of the Thames, as to the rainfall and the rivers and springs in the neighbourhood; with suggestions for the supply of London from pure waters in that district - - - *Question* 6888–6915

Brodie, Sir Benjn., Bart. (25th March 1868) - *Page* 430
On the effect of sewage discharged into rivers; and on the self-purification of streams - *Question* 6979–91
On the application of sewage to land - 6992–4
On the methods adopted for the determination of organic matter in water - - 6995–7009
Sewage in water - - - - - 7010–14
As to the action of soft water on iron and lead pipes - - - - - 7015–8
Effect, on soft water, of a long flow in aqueducts - - - - - 7019–21
On soft and hard waters - - - - 7022–7
Sewage in water - - - - 7028–35
Utilization of sewage - - - - 7036–40
Effect of drinking water on the health of towns 7041–4

Brown, T. C. (18th March 1868) - - *Page* 413
On the rainfall at Cirencester; and the storage in the permeable strata of the neighbourhood. Suggestions in regard to the utilization of the springs in the oolite - - - - *Question* 6838–49

Burstal, Capt. E., R.N. (23rd May 1867) - *Page* 219
Constitution and duties of the Thames Conservancy Board - - - - *Question* 3572–98
Quantity of water which the water companies are empowered to draw from the Thames; its effect on the river - - - - 3599–3611
Possibility of increasing the quantity - - 3612–5
Quality of the water - - - - 3616–9
Alterations of the bed of the river - - 3620–7
Quantity flowing in the Thames - - 3628–31
Proposed exclusion of sewage - - 3632–7
Formation of reservoirs in the Upper Thames 3638–9
Power of the Conservancy Board in regard to the purification of the river, locks, gaugings, &c. 3640–84
Second Examination (18th March 1868) - *Page* 417
Proceedings of the Thames Conservancy Board as to the exclusion of sewage from the Thames, and its utilization on land, &c. Reports of chemists thereon - - - - *Question* 6851–62

Clutterbuck, Rev. James (13th March 1867) *Page* 107
Geological nature of the Thames basin; percolation and storage of the water therein, particularly in the chalk strata - - - *Question* 1782–1847
On the rainfall in the Welsh district, and quantity of water obtainable therefrom - - 1848–66
On the Thames basin (*continued*) - - 1867–93

Dale, Thomas (21st February 1867) - - *Page* 71
His engineering experience - - *Question* 1061–5
Comparison of soft and hard water - - 1066–87
Quantity required per head - - 1088–95
Particulars as to the water supply of Hull, and as to the constant service system - - 1096–1119
General particulars of witness's project for supplying water from the Lake district to various towns in Lancashire and Yorkshire - - 1120–1301
On the supply of Hull - - - 1302–5

Denton, Bailey (7th March 1867) - - *Page* 94
On water supply and land drainage generally, *Question* 1529–31
Sufficiency of the Thames to supply London; proposal of witness on the subject - - - 1532–46
Area of drainage, rainfall, &c. in the Upper Thames Basin - - - - - 1547–9
Effect of drainage and subterranean storage - 1550–4
Further particulars as to his project *Question* 1555–1602
Proposed interception and utilization of the sewage, 1603–22
Further evidence as to his project - - 1623–75
Sewage interception, &c. - - - 1675–82
The Thames sufficient as a source of supply for London, and preferable to sources in Wales or Cumberland, 1673–93
On the quality of the present London waters, 1694–1706

Duncan, Thomas (21st March 1867) - - *Page* 122
On the supply of water to Liverpool, present and future *Question* 2097–2403
Remarks on the project for supplying London from Wales - - - - - 2404–28
On the municipal control of water and gas-works, 2429–33
On the supply of Liverpool (*continued*) - 2434–54

Eachus, G. E. (27th March 1867) - - *Page* 155
Sources of water should be applied only to the supply of towns in the locality near them, and not to towns at a distance - - - *Question* 2607–33

Ewens, G. W. (23rd May 1867) - - *Page* 224
Information as to certain large springs in Hampshire, from which witness conceives the metropolis might be supplied; project for the purpose *Question* 3685–3796

Farr, Dr. William (8th May 1867) - - *Page* 172
On the analyses of London waters published by the Registrar-General - - *Question* 2844–62
Self-purification of rivers - - - 2863–4
On the outbreak of cholera in the east of London in 1866, and the connexion of the water supply therewith - - - - - 2865–82
Comparison between hard and soft water - 2863–4
Conditions of purity of water; supplies of London and Paris - - - - - 2885–95
Influences of water supply on the mortality of towns, 2896–2928
Present condition of London water - - 2929

Firth, Josiah (20th June 1867) - - *Page* 296
Comparison of hard and soft water as used in the cloth manufacture - - *Question* 5212–5319

Frankland, Dr. E. (27th February 1868) - *Page* 338
On the method of analysing potable waters, *Question* 6191–9
On the quality of the water from the Welsh and Lake districts - - - - - 6200–14
On the quality of the waters supplied to the metropolis - - - - - 6215–58
On hard and soft waters - - - 6259–68
On the system of constant service - - 6269–70
Quality of Welsh and Cumberland waters - 6271–7
On the organic contamination of drinking waters 6278–6351
Comparison between hard and soft waters - 6352–69
On the sewage contamination of the Thames, 6370–6417
Filtration - - - - - - 6418–25
Conditions of good drinking water - - 6426–8
Sewage contamination - - - 6429–32

Fulton, Hamilton H. (16th May 1867) - *Page* 216
Explanation of his project to supply London with water from the head streams of the Wye, *Question* 3446–3571
Second Examination (30th May 1867) - *Page* 246
Further particulars as to his project *Question* 4078–4171

Greaves, Charles (6th June 1867) - - *Page* 291
Sources of supply of the East London Waterworks Company - - - *Question* 5121–31
Capacity of increase from the river Lea - 5132–41
Quantity required for supply of London; experiments to determine this - - - - 5142–67
Quality of water from the Lea - - 5168–76
Capacity of the Thames basin generally for water supply - - - - - 5177–87
Effect of exclusion of sewage from the Lea - 5188–93
Springs in the chalk - - - 5194–5201
On the constant service system as applied to poor districts - - - - - 5202–10
Separation of supplies for different purposes 5210–11

Harrison, John Thornhill (9th May 1867) *Page* 179
On the rainfall and evaporation in the Thames basin; the quantity discharged by the river; the storage in the subterranean reservoirs; the geology of the district; and various other data as to the Thames basin generally - - *Question* 2931–3110

HASSARD, RICHARD (14th February 1867) - *Page* 44
His experience in regard to the supply of Dublin, *Question* 546–584
General explanations of the project of himself and Mr. Hemans for supplying London from the lakes of Cumberland and Westmoreland - 585–604
Rainfall in the district - - - 605–623
Project as regards Haweswater - - 624–655
As regards Thirlmere - - - 656–672
As regards Ullswater - - - 673–703
General explanations - - - 704–712
Tunnel from Thirlmere to Ullswater - 712–717
Catchwater drains - - - - 718–729
Conduit to London - - - - 730–754
Geological character of the ground - 755–757
Second Examination (20th February 1867) - *Page* 53
Particulars as to the Dublin waterworks (at commencement of evidence).
Lead workings in Ullswater - *Question* 758–764
Construction of conduit - - - 765–769
Alterations of levels of lakes - - 768–772
Supply of provincial towns along the line of conduit, 772–777
Discharge of large water-pipes, and of conduits, 778–795
Tunnel under Kirkstone Pass - - 795–799
Conduit to London - - - - 800–817
Proposed store reservoir at Edgeware - 818–824
Geological nature of the line of conduit - 825–838
Edgeware reservoir - - - - 839–845
Estimate for the project - - - 846–851
Provincial towns proposed to be supplied on line of conduit - - - - - 852–859
Present and future demand of water for London, 859–883
Additional supply from Bala Lake - - 884–898
Supply of provincial towns - - - 899–901
Financial scheme, with cost of water in Liverpool, Manchester, and Glasgow. Proposed water rates, &c. - - - - - 901–944
Aberdeen waterworks - - - 945–946
Supply of provincial towns - - - 947–957
Comparison of soft and hard water - - 958–963
Objections to Welsh project, as to insufficiency of rainfall - - - - - 964–978
Do. as to nature of drainage area and quality of water, 979–1032
Ditto as to reservoirs - - - 1033–1037
Ditto as to mineral workings - - 1038–1045
Ditto as to reservoirs - - - 1046–55
Ditto as to mineral workings - - 1056–8
Comparative cost of obtaining water by Lake and Welsh projects - - - - 1059–60
Estimate for Lake project (at end of evidence).
Third Examination (19th March 1868) - *Page* 426
Answer to Mr. Bateman's objections to the Lake project, and further explanations in reference thereto, *Question* 6916–78
Fourth Examination (26th March 1868) - *Page* 442
Answer to the objections of Mr. Bateman to the Lake project, and comparison of the same with that from Wales - - - *Question* 7149–82

HAWKSLEY, THOMAS (27th March 1869) - *Page* 137
General remarks on the project for supplying London with water from North Wales - *Question* 2455–64
Rainfall in Wales, &c.; probable quantity of water procurable - - - - - 2465–87
Quantity of water required for London - 2488–2503
Quality of water most suitable for the metropolitan supply - - - - - 2504–15
Quantity at present used in London - 2516–24
Further remarks on the Welsh project - 2525–33
Liability of stoppage in the conduit from frost or other interruption - - - - 2534–48
Water supply of Paris - - - 2549–51
Supply of London from the Thames - 2552–6
On the constant service system - - 2557–63
On the municipal control of waterworks - 2564–6
Comparison of hard and soft water - - 2567–8
On the supply of Liverpool - - 2569–77
On the Welsh and Lake projects for supplying London, 2578–91
On the population of the basins of the Thames and the Severn, with tables - - - 2591–5
Action of soft water on iron and lead pipes 2596–2601
Supply of Paris - - - - - 2602
Quantity of water passing down the Severn - 2603–6
Second Examination (6th June 1867) - - *Page* 286
Capacity of the Thames to supply London; quantity which might be taken therefrom - *Question* 5055–73
On the self-purification of streams; instance of the rivers at Sheffield and Leicester *Question* 5074–81
On the communication of cholera by germs in drinking water - - - - - - 5082
Capacity of the Thames basin as a source of water supply - - - - - - 5083–7
Quantity per head required for London - 5088–92
On the construction of reservoirs on the Upper Thames, with a view of increasing the supply - 5093–6
Population and sewage in Thames basin - 5097
Comparison of hard and soft water - - 5098–9
On the constant service system - - 5100–5
Sufficiency of the Thames - - - 5106–7
Hard and soft water - - - 5108–5112
Effect of abstraction of water on the navigation of the Thames - - - - - - 5113–5
Supply to the poor - - - - 5116–9
Keeping qualities of hard and soft water - 5120
Third Examination (10th December 1868) - *Page* 482
On the deficiency of water supply during the year 1868; and on the construction of reservoirs for storage - - - *Question* 7490–7537

HEMANS, GEORGE WILLOUGHBY (13th February 1867), *Page* 27
Has elaborated his project in connexion with Mr. Hassard - - - *Question* 287–292
Quantity of water required in London, present and future - - - - - - 293–299
General description of Lake project - - 300
Proposed conduit to London - - 301–303
Further general description - - - 304–306
Clearness of the water - - - 307–308
Rainfall, and quantity of water available - 309–333
Haweswater Lake - - - 334–339
Absorption and evaporation - - 340–341
Peat in the district - - - - 341–347
Project as regards Haweswater - - 348–362
Ditto as regards Thirlmere - - - 362–378
Ditto as regards Ullswater - - - 378–399
Tunnel under Kirkstone Pass - - 399–402
Analysis of the water - - - 403–404
Lead mines in the district - - - 405–413
Financial proposition; rates for water - 414–420
Rainfall in Wales - - - - 421–428
Conduit - - - - - 429–433

HENNELL, THOMAS (20th March 1867) - *Page* 115
Explanations as to his project for supplying London with water brought by the Basingstoke canal, *Question* 1913–2040

HERON, JOSEPH (2nd April 1868) - - *Page* 454
Particulars as to the water supply of Manchester, *Question* 7269–7403

HOLMES, S. F. (6th June 1867) - - *Page* 273
On the water supply of Sheffield *Question* 5774–4963

HOMERSHAM, S. C. (12th March 1868) - *Page* 406
Particulars as to various works erected by him for supplying spring water softened by Dr. Clark's process; and as to the supply generally from chalk springs and wells - - *Question* 4762–6837

JACKSON, JOHN (6th June 1867) - - *Page* 279
On the water supply of Sheffield - *Question* 4964–71

JUBB, SAMUEL (20th June 1867) - - *Page* 299
Comparison of hard and soft water as used in the cloth manufacture - - - *Question* 5320–95

LEACH, S. W. (30th May 1867) - - *Page* 250
On the volume of water in the Thames, *Question* 4240–70
Proposed store reservoirs in the upper part of the river - - - - - 4271–86
Improvements in the river; proposed exclusion of the town sewage; self-purification of the stream, 4287–99
Further remarks on the volume in the Thames, and its proposed increase by store reservoirs - 4300–20

LETHEBY, Dr. HENRY (29th May 1867) - *Page* 232
Analysis of the London waters - *Question* 3859–69
Qualities of Loch Katrine water - - 3870
On peaty water - - - - 3871–2
Pump waters in the city of London - - 3873–9
Opinion as to the general quality of the waters supplied to London - - - - - 3880–7
Purification of the Thames by exclusion of the sewage - - - - - 3889–91
Self-purification of rivers generally - - 3892–7
On the spread of cholera by drinking water 3898–3918
Water supply to various provincial towns, and its effect on their rate of mortality - - 3918–26

Quantity required per individual - - 3927–30
Comparison of soft and hard waters - 3931–42
Increase of London supply - - - 3943–46

McClean, J. R. (27th June 1867) - - *Page* 307
Information as to the project of witness and the late Mr. Blackwell for supplying London with water taken from the Thames at Medmenham, and for improvements in the river incident thereto *Question* 5498–5586
On the constant service system; particulars as to the supply by witness of towns in Staffordshire, 5587–5636
Sufficiency of the Thames for the supply of London, 5637–8
Hardness and softness in water - - 5638–42
Proportion of rainfall available in Thames basin 5643–5
Further particulars as to his Thames project 5646–52
Do. as to his Staffordshire waterworks - 5653–71
Hard and soft water - - - 5672–5
Improvements of the Thames - - 5676–82
On the supply of provincial towns generally in the Midland districts - - - - 5683–5714
Quantity and quality of water in the Thames 5715–22
Comparison of water from different strata - 5723–8
Supply to the Midland counties - 5729–35

Macneill, Telford (27th June 1867) - *Page* 320
Explanations as to his proposed scheme for supplying London, by diverting water from the Thames, and filtering it through the Bagshot sands, *Question* 5815–5958

Meeson, Rd. (18th March 1868) - *Page* 419
Information as to large springs existing in chalk pits belonging to witness at Gray's Thurrock, Essex, *Question* 6863–7

Miller, Dr. W. A. (5th March 1868) - *Page* 436
Comparison between soft and hard water, *Question* 7045–58
Peat in water - - - - - 7059–61
Sewage in water; self-purification of rivers; condition of the Thames - - - - 7062–71
Nitrates in water, as evidence of sewage contamination - - - - - 7072–7
Application of sewage on land - - 7078–80
Sewage in water - - - - 7081–4
On the constant service system - - 7085–6
Power of soft water to absorb gases - - 7087
Self-purification of streams - - - 7088–9
Effect of filtration - - - - 7089–90
Peat in water - - - - 7091
Aeration of water - - - - 7092–3
Most essential conditions for drinking water 7094
Hardness and softness - - - 7095–7
Nitrates in water - - - - 7098–7103
Modes of analysis - - - - 7104–16
Action of soft water on lead - - 7117–21
Effect of manured lands in the chalk districts - 7122–3
Hardness and softness - - - 7124–6

Morris, W. R. (26th February 1868) - - *Page* 333
Particulars as to the supply furnished by the Kent Waterworks Company - - *Question* 6094–6149
On the constant service system - - 6150–6160
Consumption per head - - - 6161– 8
Nitrates in water - - - 6169–71
Further remarks on the Kent waterworks - 6172–90

Muir, James (29th May 1867) - - *Page* 239
Particulars as to the New River Company; their supply to London, &c. - *Question* 3947–4025
Dr. Clark's softening process - - 4026–8
Capability of the Lea and the Thames for yielding increased supplies - - - 4029–53
On the constant service system - - 4054–77
Analysis of water from Amwell well (at end of evidence).

Mylne, R. W. (6th June 1867) - - *Page* 279
On the supply of London by the New River Company - - - - *Question* 4972–82
Explanations as to witness's project for increasing and remodelling the supply obtainable from the basin of the river Lea - - - - 4983–5054

Odling, Dr. Wm. (27th February 1868) - *Page* 356
On the quality of waters in the Welsh and Lake districts - - - *Question* 6433–6
Comparison between hard and soft waters - 6437–9
On the Welsh and Lake waters (*continued*) - 6440–6
On the sewage in the Thames water, and the self-purification of rivers - - - 6447–58
Nitrates in water - - - - - 6459–62
On the general quality of the water supply from the Thames basin - - - - 6463–7
On organic impurities in water - - 6468–84

Ormsby, A. S. (5th June 1867) - - *Page* 257
Particulars as to his project for supplying London with drinking water collected from the rainfall on non-absorbent artificial surfaces - *Question* 4443–4560

Orton, Thos. (30th May 1867) - - *Page* 248
On the cholera epidemic in the east of London in 1866, and its connexion with the water supply, *Question* 4172–4239

Parkes, Dr. E. A. (9th May 1867) - - *Page* 194
Communication of diseases by drinking water containing sewage - - - *Question* 3111–23
Comparison between hard and soft water - 3124–38
Action of soft water on lead - - 3139–42
Filtration - - - - - 3143–6
Classification of potable waters - - 3147–51
Character of the London water - - 3142–61
Constant service system - - - 3162–9
Communication of diseases by water - 3169–76
Quality of the water of the Thames - 3177–88
Changes in water by flowing through long conduits, 3189
Communication of diseases by water - 3190–4
Self-purification of the river Itchen - - 3195–9
Influence of the water supply on the health of troops; comparison in this respect of hard and soft waters, 3200–18
Supply of Southampton - - - 3219–20
Quantity of water per head required by troops 3221–7
On the quality of Thames water; effect of exclusion of the sewage - - - - 3228–37
Influence of different qualities of water on health; hard and soft water - - - 3238–55

Playfair, Dr. Lyon, C.B. (10th April 1867 - *Page* 156
General quality of the water supplied to London, 2634–45
Comparison between hard and soft water 2646–2719
As to the constant service system - - 2720–4
Action of soft water on lead pipes - - 2725
Influence of water supply on the mortality of towns, 2726–8

Quick, Joseph (26th February 1868) - - *Page* 328
Particulars as to the supply given by the Grand Junction Company - - *Question* 5982–6004
Increase possible from the Thames - - 6005–8
Quality of the water - - - 6009–10
On the constant service system - - 6011–56
Cost of pumping - - - - 6057–8
Quantity consumed per head - - 6059–63
Filtration - - - - - 6064–9
Further remarks on the constant service system 6070–93

Ramsay, Professor A. C. (13th March 1867) - *Page* 104
Geological character of the Welsh district *Question* 1707–12
Peat therein - - - - 1713–20
General nature of land surface - - 1721–29
Mineral workings in the district - - 1730–42
Nature of the district of Bala Lake - - 1743–8
Further particulars as to the strata in the Welsh district - - - - - 1749–71
On the district of the Cumberland lakes - 1772–6
On the Welsh district (*continued*) - - 1777–81

Rawlinson, Robert (6th March 1867) - *Page* 81
His engineering experience - *Question* 1306–22
On the formation of reservoirs - - 1323–5
Observations on the Welsh project, the rainfall, &c. 1326–42
Comparison between hard and soft water - 1343–7
On the proposed Welsh reservoirs - - 1348–58
On the quality of the Thames water - 1359–60
Hard and soft waters - - - 1361–80
On the supply of Liverpool from Bala Lake 1381–1423
Hard and soft water - - - - 1424
General conditions of rainfall - - - 1425

Second Examination (7th March 1867) - *Page* 87
On the nomenclature used in questions of water supply - - - - *Question* 1426
General conditions of rainfall - - 1427–38
Supply of Liverpool - - - - - 1439
On rainfall - - - - - - 1440
On the construction of reservoirs - - 1441–7
On rainfall - - - - 1448–52

Third Examination (13th March 1867) - *Page* 113
On the action of soft water on wrought-iron pipes, *Question* 1894–1909
On the quantity delivered by pipes of certain sizes, 1910–11
On the waste of water by defective fittings - 1912

REMINGTON, GEORGE (5th June 1867) - *Page* 253
Particulars of his project for supplying London from the river Dove in Derbyshire *Question* 4321–4442

RENDLE, W. (11th March 1868) - - *Page* 404
As to the defective supply of water in the borough of Southwark, and the necessity of the constant service system - - - - *Question* 6749–61

SIMON, JOHN (8th May 1867) - - *Page* 165
On the supply to the City of London *Question* 2737–44
On the constant service system - - 2745–50
Pollutions of the London water, and their effect in producing disease - - - 2751–64
Action of soft water on lead - - 2765–6
Constant service system - - - 2767–76
Comparison between soft and hard water - 2777–94
Filtration of London waters - - 2795–7
Quantity of water required per head - 2798–2803
On the general quality of the supply to London, 2804–26
Constant service - - - - 2827–33
Hardness and softness - - - 2834–6
On the interception of sewage from the Thames, 2837–42
Constant service - - - - 2843

Second Examination (26th March 1868) - *Page* 440
On an outbreak of typhoid fever at Guildford, believed to be caused by impure drinking water, and on the control of water companies in general, *Question* 7127–34
Effect of sewage in water; self-purification of streams, 7135–48

SIMPSON, JAMES (5th June 1867) - - *Page* 261
On the present supply of water from the Thames, and the general eligibility of the river for the future supply of London - - *Question* 4561–4611
Remarks on the Welsh project - - 4612–10
On the constant service system - - 4621–22
Quality of the London water - - 4623–37
Exclusion of sewage from the Thames - 4638–9
Future quantity derivable from the Thames 4640–51
Powers and operations of the Thames Conservancy Board - - - - - 4652–55
Sewage in the Thames - - - 4656–70
Rainfall in the Thames basin - - 4671–7
Quality of the Thames water - - - 4678–85
Objections to Welsh project - - 4685–91
Analysis of London waters - - - 4692–7
The constant service system; difficulties with it in America - - - - - 4698–4717
Quantity required for London - - 4718–22
Soft and hard water; supply of Aberdeen and Paris - - - - - 4723–32
Filtration - - - - - - 4733–4
Separation of supplies for different purposes 4735–8
The Registrar-General's reports on London waters, 4739–40
Distribution of water in London - - 4741–3
Supply to the poor - - - - 4744–50
Action of soft water on iron and lead - 4751–8
Quantity required for London - - 4759–64
Volume of the Severn - - - 4765–9
Rates for water - - - - 4770–3

SMITH, Dr. R. ANGUS (2nd April 1868) - *Page* 445
On the examination of drinking waters as regards organic matter: example from the Clyde 7183–95
Self-purification of streams - - 7196–7200
Safety of water once affected with sewage - 7201–3
Application of sewage to the land - - 7204–7
Further remarks on organic matter in water 7208–11
Peat in water - - - - - 7212–4
The Thames as a source of supply - - 7215–7
Hardness and softness in water - - 7218–22
Fouling of water in cisterns - - - 7213–8
Further remarks as to organic matter in waters 7229–58
Comparison of hard and soft waters - 7259–65
Action of soft water on lead - - 7266–8

SYMONS, GEORGE JAMES (14th February 1867) *Page* 34
On the rainfall in the Lake district of Cumberland and Westmoreland - - *Question* 434 to 466
On the rainfall in North Wales - - 467–506
Ditto in the Lake district; on evaporation, absorption, &c. - - - - - 507–525
Ditto in Wales - - - - 526–545

Second Examination (10th April 1867) - *Page* 161
On the rainfall in Mr. Bateman's Welsh district, *Question* 2729–36

TAYLOR, JOHN (9th December 1868) - - *Page* 480
Quantity of water supplied to London during the summer months of 1867–8 *Question* 7458–9
Effects of the drought of 1868 on various towns supplied by gravitation - - - 7460–89

THORPE, JONATHAN (27th June 1867) - *Page* 316
Quantity of water taken from the Thames by the London companies - - - *Question* 5736–46
Additional quantity which might be obtained by improvements in the river - - - 5767–59
Powers of the Conservancy Board for purifying the Thames, and manner in which they have been carried into execution - - - - 5760–93
General improvements of the river - 5794–5814

WANKLYN, Professor J. A. (20th June 1869) - *Page* 301
Results of chemical examination of the waters supplied to London - - - *Question* 5396–5417
On the processes of analysis for organic matter, with description of a new process used by the witness, and comparison with other methods - - 5418–40
Constant service - - - - 5441–2
Further remarks on the London waters - 5443–51
Further remarks as to mode of analysis - 5452–82
Self-purification of streams - - - 5482–7
Hardness and softness in water - - 5488–97

WAY, JOHN THOMAS (7th March 1867) - *Page* 90
Analysis of water from the Lake district, *Question* 1453–79
On waters from Wales - - - 1480–83
On the geological strata most favourable for water collection - - - - - 1484–8
Action of soft water on lead pipes - - 1489
Ditto on iron pipes - - - - 1490–8
Comparison between hard and soft water 1499–1520
On the pollution of rivers by manufactories - 1521–8

WHALLEY, G. H., M.P., (20th March 1867) - *Page* 119
General remarks on the Welsh project, and on the district forming the gathering ground for the same - - - - *Question* 2041–7
Mineral workings in the district - - 2048–65
Further remarks on the project generally - 2066–96
